Abstract

Does visible high performance show that no support is needed? This paper sets out the Polymathic Neurodivergent Profile (PNP) as a descriptive, non-diagnostic framework for a rare but practically important pattern: unusually strong cross-domain learning, structural pattern transfer between fields, intense self-directed research, and high output in complex, high-interest domains, coexisting with clinically significant difficulty in routine administration, pacing, timekeeping, task-switching, and low-stimulation procedural work. The central proposition is the Capability-Adjustment Fallacy: the institutional inference that visible high performance is evidence that reasonable adjustments are unnecessary. That inference is unsafe, and is contradicted by existing clinical guidance. NICE CG142 already directs professionals to recognise the potential discrepancy between intellectual functioning and adaptive functioning, and modern strengths-based assessment treats the same neurodivergent trait as advantage or impairment depending on context. Beyond naming the pattern, the paper documents a live case, the author's own profile, across three separately kept documentation streams (clinical assessment, a court record and a dated research corpus); sets out a priority and convergence analysis with Hernández-Espinosa and colleagues (PNAS Nexus, 2026), whose subject is artificial agents, and with a formal result that names their argument as its conceptual foundation (Gumbau Mezquita, 2026), the author's timestamped manuscripts preceding both; and states pre-committed abandonment conditions, operational measures and the incremental-validity test the construct must pass or be discarded. The aim is neither to medicalise polymathy nor to use ability as immunity from ordinary process, but to prevent a recurrent error: the conversion of a person's strengths into evidence against their needs.

Version 1.11 sets the paper on the programme's presentation standard; corrects its account of who signed the time of the record of 8 December 2024, of two companion papers' results and of the status of the ARC Theory's laws; and restates its case records and its reading of the 2026 alignment results at their true strength. Appendix A lists every version and correction, with its date.

Paper C, a standalone working paper outside the ARC Theory and its experiments series: it documents a profile, tests no part of the theory and is load-bearing for no law; it bears on Law V, the ARC Embedding Law (added on 24 September 2026 and registered as a law on 15 October 2026 in version 1.103 of the theory registration, a law under test; its mathematics in development), only as a dated record (Section 8.1). Working paper, version 1.11, 29 October 2026; first published 3 July 2026; Appendix A lists every version and correction. Recorded on OSF as *Paper C · Standalone · Polymathy and Neurodivergent Cognition: the Polymathic Neurodivergent Profile (PNP) and the Capability-Adjustment Fallacy*, DOI 10.17605/OSF.IO/RBHDP. 1 Introduction

When a person who does some demanding things well asks for help with tasks that look easier, clinics, courts, universities and employers have to decide whether the visible performance shows that no support is needed. This paper answers that it does not. It names the opposite inference the Capability-Adjustment Fallacy, shows that clinical guidance contradicts it and that the statutory architecture of reasonable adjustments is incompatible with it, and sets out a profile that the fallacy misreads, the Polymathic Neurodivergent Profile: advanced performance in selected domains alongside marked difficulty in routine procedural work. The paper brings together three fields, clinical assessment, access to justice and AI alignment research, and assumes that no reader knows all three. Its aim is neither to medicalise polymathy nor to use ability as immunity from ordinary process, but to prevent a recurrent error: the conversion of a person's strengths into evidence against their needs.

The contemporary neurodiversity literature has exposed a long-standing weakness in diagnostic and institutional reasoning: a tendency to recognise *difficulty* without adequately recognising *form, pattern, and unevenness* (Manalili et al. 2023). Autism and adjacent neurodevelopmental profiles are still often described primarily through deficits, even as a growing body of work argues that assessment should also identify strengths, skills, and interests, because these shape both lived experience and support needs (Woods and Estes 2023; Russell et al. 2019).

This matters most for a particular kind of adult: one whose profile is neither global impairment nor smooth giftedness, but *radical asymmetry*: advanced performance in selected domains alongside marked dysfunction in others. This paper names one version of that asymmetry the **Polymathic Neurodivergent Profile (PNP)** and advances a single governing principle:

> Capability describes what can be done under favourable cognitive conditions. Disability describes where a person is substantially disadvantaged by the environment, the process, or the demand structure. Both can be true at once.

That sentence is the functional heart of the paper. It is also the proposition that institutions, courts, clinics, universities and employers must understand before they can interpret such a person fairly. The paper goes further than naming the pattern: it documents a live instance across three separately kept record types, and it reads the pattern beside a set of 2026 results in AI alignment that have made diversity among artificial agents a research question rather than a slogan.

Our contributions are as follows.

1. **A named, falsifiable descriptive construct (PNP)** with six operational components, each individually grounded in existing peer-reviewed literature, and pre-committed conditions under which the construct should be abandoned, set out in Section 4 (Table 1) and Section 10.
2. **A named institutional error (the Capability-Adjustment Fallacy)** with its clinical refutation (NICE CG142; DSM-5-TR masking; domain-specific executive function) and its legal refutation (Equality Act 2010 ss. 20, 149(6); CPR PD1A), set out in Sections 5 and 12.
3. **A three-stream documented case** in which the same person's clinical record, court record, and timestamped research corpus jointly instantiate the profile and the fallacy, making the framework checkable rather than anecdotal, set out in Section 7.
4. **A convergence analysis** connecting the profile to results in AI alignment: agent diversity as a counterbalance under a neurodivergence analogy (Hernández-Espinosa et al. 2026) and the structural insufficiency of external verification (Gumbau Mezquita 2026), with a precise, timestamp-anchored account of what preceded what, set out in Section 8.
5. **A field-level implication**: cognitive monoculture as an alignment risk, linking the clinical literature to the research programme's Papers III, IV.d and X, set out in Section 9.

Section 2 states what the paper does and does not show. Section 3 sets the profile against three literatures: strengths-based assessment, monotropism and hyperfocus, and twice-exceptionality. Section 4 defines the Polymathic Neurodivergent Profile, states its mechanism in the author's own voice and sets beside it the published retrospective literature. Section 5 states the Capability-Adjustment Fallacy, and Section 6 follows it through education, employment, the courts and artificial intelligence. Section 7 documents a live case in three separately kept evidence streams, Section 8 records the priority and convergence chain, and Section 9 draws the field-level implication for alignment research. Section 10 gives the operational measures and the conditions under which the construct should be abandoned; Sections 11 and 12 state what a clinical report and a court can properly do with the profile; Section 13 gives the limitations and the ethics statement, and Section 14 concludes. Appendix A lists every version and correction, Appendix B the paper's dated records with the kind of timestamp each carries, and Appendix C its notation and glossary.

2 What this paper does and does not show

Credibility requires the boundary of the claim to be stated plainly and kept.

It claims: that there exists a recurring, describable pattern of cross-domain high ability combined with disability-linked impairment in routine procedural functioning; that this pattern is currently under-described by deficit-only and credential-centric models; that describing it is expected to improve the accuracy of clinical formulation and the fairness of institutional treatment, which Section 10 sets as a research question; that the supporting components are individually grounded in existing literature; and that one documented instance exists whose records are open to qualified scrutiny.

It does not claim: that "polymathy" is or should become a diagnosis; that PNP is a validated clinical entity (it is a hypothesis); that every highly able neurodivergent person fits the profile; that the profile confers superiority rather than unevenness; that documenting it guarantees any legal outcome; that the author's cognition caused any external research result; or that artificial intelligence creates the underlying cognitive pattern. PNP is offered as a descriptive construct to be tested, refined, or refuted, not as a discovery to be announced.

Working status and disclaimer. This is a conceptual, clinical-formulation, and policy working paper. It is not a medical diagnosis, not a substitute for clinical assessment or legal submissions, and not a request for preferential treatment. "Polymath" is used throughout as a descriptive label, not a diagnostic category: it has no standing in psychiatric nosology, disability law, or educational classification. Its analytical content is exploratory: the incremental-validity test set out in Section 10 is the intended future evaluation, drafted as a programme follow-on study (Unit 64), preregistered by timestamp (first anchored in Bitcoin block 962066 on 12 August 2026) and awaiting human submission; it has not been run. The single operative claim is functional: capability in one domain does not remove support needs in another.

Reading key. This paper documents a *profile*, not a theory: the Polymathic Neurodivergent Profile and the Capability-Adjustment Fallacy form an analytical construct that sits beside the ARC Theory rather than inside it. Its own quantitative first-mentions are labelled exploratory. Section II.A.8 of the Eden Protocol's philosophical statement (version 2.9) sets the programme's doctrine that values must be embedded at the foundation rather than retrofitted from outside against the nearest prior documents; this paper's construct is set against its literatures in Section 3.

Epistemic status. What this programme names Laws are conjectures, each a law under test until a registered test returns its verdict. Laws I to III were registered on 8 September 2026, and Laws IV and V,

added on 24 September 2026, were registered as laws on 15 October 2026 in version 1.103 of the theory registration, their mathematics in development (version 1.1, 7 October 2026). Law IV is not yet tested. Law V is a law under test. Its placement limb, P21, is supported on the performance axis only, under the registered test, by the programme's own run (Unit 83, 28 October 2026, DOI 10.17605/OSF.IO/MN73W; results: DOI 10.17605/OSF.IO/98HKR): family-dependent, with its mechanism axis not evaluable, which is not support for the information-asymmetry mechanism, and one disclosed recovery amendment. Its build-order limb, read on P12, is undecided, since P12 is untested. The programme's first registered study, Unit 06, a classification audit that tests no law, was registered on 1 October 2026 (DOI 10.17605/OSF.IO/RV2B5) and run on 6 October 2026; it is reported in full with its five deviations, as administratively incomplete, with no inferential verdict (results DOI 10.17605/OSF.IO/4BPHG). Every quantity in this paper is operationally defined, and established-law standing is claimed nowhere. The registered programme exists to earn that standing, or lose it, by measurement, replication and survived refutation.

3 Related work

3.1 The turn to strengths-based assessment

The strongest single foundation for this paper is that good autism reporting is no longer expected to describe deficits alone. NHS adult-assessment guidance states that a report should record whether the person is autistic, what the person is good at, what they may need help with, and whether other conditions were found. NICE CG142 frames adult assessment as a comprehensive process covering childhood and adult presentation, functioning, coexisting conditions, sensory sensitivities, and attention to detail (NICE 2021).

Woods and Estes (2023) developed the Survey of Autistic Strengths, Skills, and Interests precisely because clinicians and autistic people experience current approaches as overly deficit-centred and insufficiently informative for support planning; the neurodiversity paradigm reframes assessment toward what autistic people *can* do, not only what they cannot (Ferreira 2025). Empirically, Russell et al. (2019) found that the most frequently described autistic traits, the ability to hyperfocus, attention to detail, strong memory, and creativity, "could be experienced either as advantageous or disadvantageous dependent on moderating influences." Cope and Remington (2022) similarly catalogue cognitive advantages in focus, memory, and creativity reported by autistic adults in the workplace.

This is the descriptive logic PNP sits inside. The point is not that strengths cancel difficulties; it is that strengths and difficulties are frequently *intertwined*, and that both are necessary to understand how a person functions. Neuro-affirming reporting guidance makes the same case at the level of practice, recommending that reports avoid crude functioning labels and instead describe strengths, difficulties, thinking style, and concrete adjustments (NAIT 2024).

3.2 Monotropism, hyperfocus, and the interest-based mechanism

If the strengths literature establishes *that* unevenness occurs, monotropism offers a mechanism for *why*. Murray, Lesser and Lawson (2005) describe autistic cognition as the tendency for attention to be pulled strongly, cognitively and emotionally, into a narrow attention tunnel, producing intense engagement with a small number of interests and difficulty engaging with stimuli outside the tunnel, with transitions experienced as costly. A self-report measure, the Monotropism Questionnaire, found both autism and ADHD associated with higher monotropism, with combined-profile respondents scoring highest (Garau et al. 2023; at the time of writing this measure was a preprint and is cited as preliminary).

Closely related, Ashinoff and Abu-Akel (2021) review *hyperfocus*, complete absorption in a task to the point where a person appears to tune out everything else, noting it is under-researched and absent

from diagnostic criteria despite being ubiquitous in autism and ADHD self-report. In ADHD clinical writing, the same phenomenon is framed as an interest-based rather than importance-based pattern of attentional regulation; this framing is clinically useful but rests largely on clinical observation, and is presented here as explanatory rather than as hard evidence.

Together these accounts are consistent with the signature PNP describes: sustained, high-output engagement with self-directed, high-interest, high-complexity material, and disproportionate difficulty with externally paced, low-stimulation, low-reward procedural tasks. The complex task is not necessarily harder; for a monotropic mind it may be more *regulating*.

3.3 Twice-exceptionality and asynchronous development

The gifted-education literature independently describes the same shape. "Twice-exceptional" refers to individuals who are simultaneously gifted and neurodivergent, whose spiky cognitive profiles show peaks in the gifted range and valleys in the impaired range, and who exhibit asynchronous development: an internal mismatch among cognitive, emotional, and procedural domains (Reis, Baum and Burke 2014; Foley-Nicpon et al. 2011). A recent systematic review notes, following Silverman, that the asynchrony of gifted development increases when high levels of intelligence coexist with major weaknesses (Rizzo et al. 2025).

Critically, twice-exceptionality is explicitly a profile, not a diagnosis: a direct precedent for the way PNP is framed here. The literature also names the social consequence PNP is concerned with: gifts and difficulties can mask each other, so that such learners' needs may not be recognised, and many "risk being overlooked, misdiagnosed, or misunderstood" (Rizzo et al. 2025). In this paper's words, such individuals can be *too able to be seen as disabled, and too disabled to be recognised as able*, and are therefore frequently misread by systems that expect ability to be uniform. Much of this literature is child-focused and US-based; its extension to UK adults is offered as a reasoned generalisation, not as direct adult evidence.

The literature on attention, systemising and retrospective trait-pattern assessment that bears on the profile's mechanism is set out beside it in Sections 4.2 and 4.3, and the 2026 results in AI alignment in Section 8.

4 The Polymathic Neurodivergent Profile

4.1 Definition

Definition 1 (Polymathic Neurodivergent Profile)**.** A Polymathic Neurodivergent Profile is a descriptive construct, stated here as a hypothesis, characterised by six interacting features, set out in Table 1.

The framework is descriptive, not taxonomic. It implies no new clinical subtype, no biomarker, and no diagnostic threshold. Its purpose is narrower: to improve formulation where standard labels capture only fragments of the picture. In some cases "autism" or "ADHD" may name the neurodevelopmental substrate while "PNP" names the strengths-based manifestation and the misunderstandings that follow from it.

The obvious question is whether this is twice-exceptionality (Section 3.3) under a new name. It is not, and the difference is what the construct has to earn its keep on. Twice-exceptionality pairs general giftedness with a co-occurring disability and is overwhelmingly a child-and-education construct. Its literature records that such learners' gifts and difficulties can mask each other, so that their needs may go unrecognised in school (Section 3.3); it does not name the inference that turns visible ability into evidence against need, or follow that inference into adult administrative, employment and legal process.

Table 1. The Polymathic Neurodivergent Profile: its six interacting components (Definition 1), each with its description and the strength of the evidence for it.

#	Component	Description	Evidence strength
1	Cross-domain depth	Not casual interest in many subjects, but repeated acquisition of serious competence across distinct fields	Observational; polymathy literature (Araki 2018; Root-Bernstein 2009)
2	Recursive pattern transfer	Extracting relational structure from one domain and using it to accelerate learning or reasoning in another; "recursive" in the ordinary structure-mapping sense (Gentner 1983; Gick and Holyoak 1983). Genuine cross-domain transfer is rare and effortful, which is part of what makes a transfer-rich profile distinctive	Strong mechanism literature; profile-level evidence observational
3	Autonomous research intensity	Deep self-directed study driven by intrinsic interest, often outside formal pathways	Consistent with special-interest depth (Grove et al. 2018)
4	Hyperfocus and immersion	Periods of unusually sustained attention, high output, and rapid synthesis in high-stimulation domains	Widely self-reported; under-researched as a construct and absent from diagnostic criteria (Ashinoff and Abu-Akel 2021; Russell et al. 2019)
5	Executive asymmetry	Disproportionate impairment in routine administration, timekeeping, correspondence, filing, scheduling, task-switching, and procedural housekeeping	Strong (NICE CG142 IQ-adaptive gap; Hill 2004; Demetriou et al. 2018)
6	Institutional misrecognition	The tendency of organisations to misread the profile because its strengths and impairments violate ordinary expectations of consistency	Strong for the outcomes (underemployment, masking and burnout literature; Buckland 2024; ONS 2021); the misreading itself inferred

PNP specifies three things twice-exceptionality (2e) does not: that the ability is *cross-domain structural transfer* rather than high ability in a single area (components 1 and 2); that the population is adults navigating administrative, employment and legal systems rather than schoolchildren; and that the pattern generates a *named, correctable institutional error*, the Capability-Adjustment Fallacy of Section 5, whose refutation is the paper's practical payload. Whether that specificity survives measurement is exactly the incremental-validity test Section 10 commits the construct to passing or failing in public.

In one sentence: *advanced capacity in complex, self-directed domains may coexist with serious impairment in externally sequenced, low-stimulation, administratively rigid systems.*

4.2 The mechanism, stated humbly: trained recursion, not innate gift

This section is stated in the author's own voice; the disclaimer that opens it binds every clause that follows. Section 3.2 described the pattern from the outside, as monotropism. What follows describes the same pattern from the inside, because how the mechanism feels to its subject is part of what the profile has to explain.

The author does not claim superior intelligence. What is claimed is a different attentional architecture: perseverative, recursive iteration on the same problem or subject-matter until the outcome-space is

substantially exhausted. Every scenario is considered; every third-, fourth- and fifth-order influence is traced; every question is asked, answered, and then re-asked from a different angle. The loop does not release its object until the object stops yielding. This is not brilliance. It is a wiring, and a costly one, whose costs are the executive-function impairments recorded as component 5 of Table 1 and evidenced across the case in Section 7.

The pattern produces the second mechanism: expertise as trained, not innate. Recursive questioning applied over decades to many domains accumulates by ordinary compounding. Since generative AI became widely available in 2023, the loop has been massively accelerated: answers that once required months of library work now return in minutes. More questions asked, more answers returned, more domains partially mastered, deeper transfer between them, expertise reinforcing expertise. The author was not born with cross-domain competence. The competence was ingrained, trained, and built up over decades of the loop running, and the polymathy documented in Section 7 is the accumulated output of that loop, not a starting condition.

The convergence is the newest point in this subsection. A study in the field now finds, on its own quantitative evidence, that sequential scaling, in which reasoning chains build on their previous attempts, outperforms parallel self-consistency at matched compute in 95.6% of the configurations it evaluated, across five open-source models and three reasoning benchmarks. Sharma and Chopra (2025) published the quantified result in November 2025. The author's independent formalisation appears in Paper II (now titled Paper II · The ARC Theory · Law I, the ARC Principle · Blinded Cross-Architecture Replication and the Retraction of a Super-Linear Estimate; first published January 2026), and the 8 December 2024 self-emailed manuscript bundle (SHA-256 `f0d1f38f`) carries the one-sided directional statement that recursion amplifies capability, with the comparison itself first formalised in Paper II.

Credit here is given in three layers: publication priority, the dated record and independent formalisation. Publication priority on the quantified 95.6% number belongs unreservedly to Sharma and Chopra. The 8 December 2024 timestamp anchors a one-sided directional statement, not the comparison. On the author's reading, the comparison is the ARC Equation's to make, since parallel width has no term in $U = I \times R^{\alpha}$ (Appendix C); that derivation was completed in 2026 by the operational definition of R and carries the date of its youngest premise. Independent formalisation is acknowledged in both directions, with no influence claimed in either; the author was unaware of the Sharma and Chopra paper when he formalised the January 2026 experiments and encountered it months afterwards (biographical attestation, offered as such).

In reasoning-token architectures that make chain-of-thought visible at scale, the field is building into machines an iterate-and-re-question loop that resembles the pattern this subsection describes. DeepSeek's R1, released January 2025 (DeepSeek-AI 2025), counts as one of the first prominent open-weights systems of that kind; the hedge is deliberate, because reasoning-model work descends from more than one lineage. From this convergence a compact hypothesis follows, rung-tagged accordingly. **HYPOTHESIS** The neurodivergent cognitive style documented in this paper may be a biological instance of the reasoning architecture that Sharma and Chopra find outperforms parallel self-consistency. If the hypothesis holds, it would explain both the polymathy (compounding cross-domain training) and the dates recorded in Section 8, since such a loop would then have been running in a single mind for years before the machines had it. Nothing in this paper tests it.

The claim is the polymathic *method*, never the stature. The book from which this paper descends (*Infinite Architects: Intelligence, Recursion, and the Creation of Everything*, print edition 2 January 2026, ebook 6 January 2026, ISBN 978-1806056200; Eastwood 2026a) already stated this position: its Author's Note (pp. 43 to 63) sets out the biographical basis and closes with a passage that binds the register.

> The ARC Principle, the Eden Protocol, the framework of caretaker doping: these are my contributions. I make no claim to have invented the components. Recursion is well understood

> in mathematics. The alignment problem has been articulated by minds far more credentialed than mine. Religious traditions have explored stewardship for millennia. What I offer is the synthesis: the recognition that these separate streams are describing the same river, and that seeing them as one changes how we must act.
>
> Michael Darius Eastwood, *Infinite Architects*, Author's Note, p. 62 (Eastwood 2026a). Quote reproduced verbatim.

The book's Introduction names Rumi, Teilhard de Chardin and Leibniz as the three individual polymaths whose independent architectures converge on the same account. They were chosen precisely because they were cross-domain synthesisers, not as any claim to their stature. Claiming the stature of Rumi, Teilhard or Leibniz would be absurd, and this paper does not; borrowing their method, which is what a research posture actually does, is a different act altogether. This subsection is the formal statement in the profile paper of the position the book had already taken in prose: the polymathic method is claimed; the stature is not.

Illustrative vignette (anecdotal, no evidential weight claimed). Offered here strictly for orientation, and clearly outside the paper's evidential apparatus. A professional from outside the field (the author's wife, a dentist) once agreed to role-play a student of the cross-domain framework. Her first question was which subject the lecture belonged to. The question has no answer, and that is the point. Cross-domain work has no home discipline, and the Capability-Adjustment Fallacy's institutional home, "which box does this person fit?", is the same question in another costume. Section 5 states the fallacy formally; this vignette is only the domestic version.

4.3 Retrospective trait-pattern assessment in the published literature, and the systemising mechanism at population scale

This subsection is placed strictly beside Section 4.2 because it is often the next question a careful reader asks: is the profile PNP names ever found in the historical record of cross-domain synthesisers? Two safety rules govern everything that follows.

The first safety rule is that this paper does not itself apply PNP, or any diagnostic category, to any named historical figure. The analytical work of connecting historical evidence to modern categories is done by others in credentialled venues, and this paper cites their work rather than reproducing it. The second safety rule is linguistic: the operative verb here is "consistent with", not "was". PNP itself takes no support from any individual retrospective case; the paper's interest in this literature is a pattern: credentialled retrospective analyses keep finding neurodevelopmental trait-patterns (ADHD-like in one, autistic in others) in history's cross-domain synthesisers. All crediting flows outward.

The retrospective literature is credentialled and it exists. Catani and Mazzarello (2019), a peer-reviewed analysis in *Brain* by clinicians at King's College London and the University of Pavia, examined the documented pattern in Leonardo da Vinci's records (chronic non-completion of commissioned work, relentless procrastination and mind-wandering, productive bursts across day and night) and concluded that attention deficit hyperactivity disorder is the most scientifically plausible modern explanation of the recorded pattern.

Two further monographs sit alongside it. Fitzgerald's *Autism and Creativity: Is There a Link between Autism in Men and Exceptional Ability?* (2004, Routledge) surveys retrospective trait-pattern assessments for a broader sample of historical figures. James's *Asperger's Syndrome and High Achievement: Some Very Remarkable People* (2006, Jessica Kingsley Publishers) develops the same register for a set including Isaac Newton and Albert Einstein. Neither monograph diagnoses; each documents a recurring trait-pattern in the historical record and cites the biographical evidence that carries it.

Underneath the retrospective register sits a mechanism claim at population scale. Baron-Cohen's hypersystemising theory identifies the drive to detect if-and-then causal patterns as one of the engines of human invention (Baron-Cohen 2020, *The Pattern Seekers: How Autism Drives Human Invention*, developed from a longer research programme on empathy and systemising in autism).

Genome-wide association work by Warrier, Baron-Cohen and colleagues reported a positive genetic correlation between autism and systemising of $r_g = 0.26$ (standard error 0.06, $p = 3.35 \times 10^{-5}$), independent of educational attainment and genetically dissociable from the social-communication component of autism (Warrier et al. 2019). The reported correlation does not diagnose any individual and does not settle prevalence for the profile this paper names. It does place systemising, as the study measured it, on a genetic axis linked to autism at the population level, rather than leaving it a purely biographical curiosity, and it is the kind of finding a reader can check.

The author's own working notes in the research corpus explored the mapping from DSM-5 ASC and ADHD criteria to the documented behaviours of celebrated historical polymaths, and contained their own section on the limits of retrospective methodology; those notes predate this paper but are cited here as working notes, not as evidence, and are consistent with the polymathic-method claim recorded in the book (the closing block of Section 4.2).

Methodological caveat (stated prominently). Retrospective assessment of historical figures is contested in the clinical literature. The dead cannot be diagnosed. Historical records carry period bias, translation loss, and selection: the records that survived may not be representative of the person's ordinary functioning, and the categories being applied are twenty-first-century constructs applied to lives lived under earlier ones. This paper accordingly treats the Catani-Mazzarello, Fitzgerald and James analyses as convergent observations by qualified authors, not as clinical facts, and PNP itself draws no support from any individual historical case. **HYPOTHESIS** The connection between the trait-patterns that credentialled retrospective analyses keep finding in history's cross-domain synthesisers, and the profile named in Section 4, is a hypothesis, not an established finding.

The closing tie is short. The book's choice of Rumi, Teilhard de Chardin and Leibniz as its exemplars (the closing block of Section 4.2) is this subsection's principle stated in prose: the individual figures remain the property of the retrospective literature that examines them, and the method is claimed as method, not as stature.

5 The Capability-Adjustment Fallacy

Definition 2 (Capability-Adjustment Fallacy)**.** The **Capability-Adjustment Fallacy** is the inference that because a person can perform a high-level task, they cannot require adjustments for lower-level procedural demands.

It appears reasonable only on the assumption that cognitive difficulty scales linearly: that anything "easier" than the hard thing a person can do must also be within reach. In neurodivergent life, that assumption frequently fails. A high-complexity research problem may be *easier* than a simple administrative task, because the former is meaningful, patterned, self-directed, and intrinsically regulating, while the latter is fragmented, externally paced, low-reward, and executive-function heavy.

This is not a rhetorical move. It is anchored in clinical guidance. NICE CG142 (recommendation 1.1.3) directs all health and social care professionals who support autistic adults to have a broad understanding of the "potential discrepancy between intellectual functioning as measured by IQ and adaptive functioning as reflected, for example, by difficulties in planning and performing activities of daily living including education or employment" (NICE 2021). DSM-5-TR records that autistic difficulties "may be masked

by learned strategies in later life", so that high apparent functioning can conceal, rather than refute, support needs (APA 2022). The executive-function literature shows that differences in autism are real but domain-specific rather than globally uniform (Hill 2004; Demetriou et al. 2018), and that everyday dysexecutive difficulties can be present even where laboratory task performance is intact. A person can therefore be cognitively advanced and adaptively impaired at the same time; in PNP that discrepancy may be extreme and institutionally confusing.

The fallacy has a practical cost: it converts evidence of competence into evidence against need. A litigant who files a sophisticated written argument may be denied extra time, filing support, or procedural clarification because the decision-maker sees capability rather than disability. That is precisely backwards. The sophistication of the substantive work shows that the person's cognitive strengths are real; it says little about whether they can manage routine procedural burdens without disadvantage.

The proper test is **functional and demand-specific**: What is the task? What cognitive, sensory, social, administrative, and time demands does it impose? Which parts of the person's profile make that task disproportionately difficult? Which reasonable changes would reduce the disadvantage while preserving fairness to others and the integrity of the process? That is a more serious analysis than asking whether the person appears intelligent.

6 Institutional misrecognition: education, employment, courts, and AI

6.1 Education

A person may be in top sets for subjects that engage their interests and at the bottom in subjects that do not. Read morally, this becomes laziness or inconsistency; read neurodevelopmentally, it may reflect interest-based attentional regulation, executive asymmetry, and sensory or social load. Uneven attainment is common in neurodivergence, and strengths-based assessment argues that it should be described as a pattern rather than a character flaw.

6.2 Employment

The outcomes data are stark. Per the Office for National Statistics' first release to identify autistic respondents, autistic adults had the lowest employment rate of any disability group (ONS 2021). The Buckland Review of Autism Employment found that only around three in ten working-age autistic people are in work, against roughly five in ten for all disabled people and eight in ten for non-disabled people; that autistic graduates are about twice as likely as non-disabled graduates to be unemployed fifteen months after graduating; and that autistic workers face the largest pay gap of any disability group (Buckland 2024). These outcomes are consistent with, though they do not by themselves show, capability going unrecognised. Masking compounds this: camouflaging is associated with higher measured ability, later or missed diagnosis, and worse mental-health outcomes (Hull et al. 2017; Cage and Troxell-Whitman 2019; Livingston et al. 2019), and sustained mismatch between expectation and support is a route to autistic burnout: chronic exhaustion, skill loss, and reduced tolerance, distinct from ordinary occupational burnout (Raymaker et al. 2020).

6.3 Courts

Legal systems combine high cognitive complexity with intense procedural rigidity: deadlines, bundles, filing sequences, service evidence, transcript requests, order review. Those demands are executive-function intensive, not intellectually simple for everyone. A litigant in person can be strong in legal reasoning and

weak in procedural administration; treating the former as proof that the latter needs no support produces unfairness, and is the Capability-Adjustment Fallacy applied to access to justice.

6.4 Artificial intelligence

Generative AI can accelerate drafting, research, and synthesis; this paper's position is that it does not originate the judgement, selection, cross-domain integration, and strategic direction that decide what to do with that output. For a person with a strong pre-existing pattern of cross-domain synthesis, AI functions as a *throughput multiplier*: it can make strengths more visible while leaving executive-function impairments untouched. The presence of AI-assisted work should therefore not be used to deny either the person's own cognitive contribution or their disability-linked support needs. This is the paper's most modest and least evidenced claim, and is offered as a reasoned position rather than a demonstrated finding.

7 A documented live case: three separately kept evidence streams

Named cognitive profiles usually rest on aggregated questionnaires or anonymised vignettes. This paper can do something unusual: present a single documented instance in which the profile and the fallacy are recorded in three documentation streams kept by different hands for different purposes (a clinician, a court, and the mail and deposit services that date the author's corpus), none of them constructed for this paper. The subject is the author, whose own account and filings enter the first two streams and whose work is the third. Section 13 addresses the ethics and the epistemics of that choice; this section states the evidence.

7.1 Stream 1: the clinical record

The author holds adulthood diagnoses of autism spectrum condition and ADHD, with independent psychiatric documentation describing the asymmetry the profile names: unusually strong self-directed learning, pattern recognition and cross-domain synthesis in high-interest domains, coexisting with clinically significant executive-function impairment in routine administration, timekeeping and procedural work. The clinical documentation is held privately for obvious reasons, and is available to qualified reviewers under appropriate conditions. Nothing in this paper asks the reader to take the clinical stream on trust: the paper's argument survives even if the reader brackets it entirely, because the other two streams are public.

7.2 Stream 2: the court record

The author has conducted complex multi-track civil litigation in person in the courts of England and Wales. The record of that litigation contains, simultaneously: substantive written work that the opposing parties engaged specialist counsel to answer, and repeated applications for modest procedural adjustments under the Equality Act 2010 and CPR PD1A, disclosed disability, and documented difficulty with the procedural demand classes the profile names (deadlines, sequencing, administrative correspondence). The record therefore contains both halves of the fallacy in a single institutional file: output treated as evidence of capability, and adjustment requests assessed against that appearance of capability. The paper takes no position here on the merits of any live proceedings; the record is cited only as a documented instance of the demand-specific asymmetry, and it is a matter of court record: the applications are the author's, and the responses to them are the court's.

7.3 Stream 3: the timestamped research corpus

The third stream is the one no questionnaire could fabricate: a dated body of cross-domain research output, whose first record's times are signed by the mail servers and whose later works are dated by their deposits (Appendix B). On 8 December 2024, the author self-emailed manuscripts totalling roughly 221,236 words; the export carries a published SHA-256 hash, and its date is carried by the provider's cryptographic signature (sender-domain DKIM with Google ARC). The corpus that followed spans AI alignment (an evaluation-blinding protocol: on the programme's own benchmark, two model families' unblinded rises did not hold in a later run that changed several things, a bundle of blinding steps among them), scaling theory (a co-scaling criterion for a vanishing misalignment fraction, proved inside a minimal model, with its measurement on real systems unsolved), mathematics (a functional-equation account of why two independent derivations of the metabolic scaling exponent converge, sent to the leading authors of both derivations), and physics-adjacent classification work on time crystals. External events bearing on the corpus's structural claims have since been recorded; the programme's graded convergence register sets each one out in its own row, gives that row an evidence class, and publishes no combined figure, since technical experiments, theorems, engineering proposals and policy developments cannot legitimately be summed as one evidential quantity (an ungraded snapshot of 2 July 2026 is kept for reference as an exploratory count, not as evidence; this paper does not itself test the convergence, and the programme's audit of how many of the convergences are independent is a draft, preregistered by timestamp and awaiting human submission: its data already exist, and its preregistered analysis has not been run). That register is public: every row names one primary source, and wherever the dates require it, priority is credited to others in plain terms.

Why the third stream matters methodologically. Component 1 of the profile (cross-domain depth) and component 2 (pattern transfer) are ordinarily the hardest to evidence: self-report is unreliable and credentials measure institutional access, not cognition. A dated corpus answers part of both problems. Its signed dates cannot be backfilled, though they rest on the mail servers' authority and the sender chose what to send and when; and the same recursion-and-correction structure is applied to quantum error correction, metabolic scaling and reinforcement-learning drift, with each application dated. Whether those domains are distinct and whether the transfer is substantive are not settled by the hash or the signature: they are matters for assessment of the documents against stated criteria, by an assessor applying them (Section 10, measures (a) and (c)). Whatever one thinks of the corpus's conclusions, its existence, dates and breadth are checkable facts, and they are the facts the profile names and that credentials do not register.

One biographical fact bears on this stream. The author did not begin as an AI-safety researcher: he began as a *creation theorist*. His December 2024 manuscripts are, before anything else, a theory of why created systems persist: recursion amplifies, and only embedded, co-scaling correction prevents amplification from becoming destruction. The AI-safety programme, the scaling-law papers, the stability criterion and the book all *derive* from that single creation-theoretic move, and each step carries its own dated record (the HRIH monograph states the hypothesis, kept apart from the programme's tested claims; Papers I to XI operationalise the move). It is a direct exhibit of PNP component 2, recursive pattern transfer: one structural idea, extracted once, applied across error correction, biology, machine learning, cosmology and theology, on checkable dates. The corpus is not a set of scattered interests; it is one theory with many testable faces.

The three streams are kept by parties with no common interest and no coordination: a psychiatrist, a court, and the mail and deposit services. They are not independent of their subject, and the third attests dates and byte integrity, not the asymmetry. The first two agree on the same asymmetry, high structured output here, impaired procedural functioning there, and the third dates the output; together they make the profile auditable for this one case rather than introspective.

8 Priority and the convergence chain

The framework's position in time can be recorded precisely, because 2026 produced results in AI alignment that this paper reads as bearing on its field-level implication (Section 9).

Table 2. The convergence chain: each dated event and the anchor that dates it.

Date	Event	Anchor
8 Dec 2024	Author's manuscripts state the control-failure thesis for AI alignment and the embedded-correction remedy; the corpus that instantiates PNP components 1 to 4 begins its dated record	SHA-256 published (OSF QASRK); date carried by the provider's cryptographic signature (DKIM with Google ARC)
May 2025	Hernández-Espinosa, Abrahão, Witkowski and Zenil circulate their preprint proving that full AI-human alignment is mathematically impossible for Turing-complete systems and proposing diversity and mutual influenceability among competing artificial agents, under the title's neurodivergence analogy, as the counterbalancing mechanism; their subject is artificial agents, and the human-cognition reading is this paper's own claim, never theirs	arXiv:2505.02581
14 Apr 2026	The same argument is published in PNAS Nexus	DOI 10.1093/pnasnexus/pgag076
26 Jun 2026	Gumbau Mezquita publishes formal results (an unverifiability theorem and a soundness-completeness-tractability trilemma) whose stated conceptual foundation is the Hernández-Espinosa paper	arXiv:2606.28639
3 Jul 2026	This paper names the profile (PNP) and the Capability-Adjustment Fallacy, and places the documented case on the public record	This paper; DOI 10.17605/OSF.IO/RBHDP

Three points of precision. First, the author's manuscripts precede the preprint by roughly five months and the formal proof by eighteen; the direction of every gap is checkable against published hashes. Second, no causal claim is made in either direction: no citation of, or connection to, the author's work by either group has been identified, which is weaker than showing that neither knew of it, so the convergence is offered as dated timing, not as influence. Third, the chain has an internal structure: a paper on diversity and influenceability among artificial agents, framed by a neurodivergence analogy, served as the stated foundation for a result on the limits of verifying alignment. Under that result's own stated assumptions, the limit is relevant to the control-failure half of what the author's manuscripts of 8 December 2024 argued; it does not establish their embedded-correction remedy, and the human-cognition reading is this paper's own, never theirs (Table 2). Every dated link in the chain can be checked at its source.

8.1 This paper and Laws IV and V

The theory has been stated with five laws since 24 September 2026. Law IV, the ARC Persistence Law, is carried by proposition P15, and Law V, the ARC Embedding Law, by propositions P12 and P21. The three propositions are registered, and the two laws were registered as laws on 15 October 2026 in version 1.103 of the theory registration; Section 2 gives their status. Their mathematics, still in development, is set out in Laws IV and V: the mathematics (version 1.1 of 7 October 2026). This paper documents a

profile and tests no part of the theory. It bears on Law V only as a dated record. Section 7.3 and Table 2 report that the author's manuscripts of 8 December 2024 state the embedded-correction remedy, and the quotation in Section 4.2 names the framework of caretaker doping among the author's contributions. In the theory registration, the book's caretaker doping is embedded correction, carried by P21, and P21 is one of the two propositions that carry Law V. The points of precision above already state that the 2026 formal results do not establish that remedy. This paper compares no correction that takes part in each revision round with correction that sees only the finished output, varies no build order, and measures no gain installed by external post-training under later capability-directed training. Nothing in it is a test of P15, P12 or P21. Naming the two laws changes nothing printed here: every claim, date and limit of this paper stands as it was.

9 Cognitive monoculture as an alignment risk

The convergence chain suggests a field-level implication that goes beyond any single person, stated here as a hypothesis. Hernández-Espinosa and colleagues argue that, among artificial agents, uniform compliance cannot deliver alignment and behavioural diversity is protective. If an analogous point holds for the people who do the research, the composition of the research field itself becomes a safety variable: uniform minds, trained in the same institutions on the same curricula, tend to miss the same things in the same direction at the same time. That would be a monoculture risk, invisible from inside the monoculture.

The research programme this paper belongs to offers three concrete instances (offered as exploratory analysis; none of this paper's own quantitative content has yet been tested). Paper IV.d reports that on the programme's own benchmark, two model families' unblinded rises did not hold in a later run that changed the responses, prompts, depth levels and Gemini model and added blinding steps; the author's own code review in October 2026 found defects in exactly those runs, so no single cause is claimed, and the finding is not yet shown beyond that benchmark. If such results hold, unblinded scoring is a failure mode that can persist across a field partly because evaluators share assumptions about their own neutrality. The Foundational paper sets out one recursive-amplification structure that it reads across quantum error correction, biological scaling and machine reasoning; drawing that map at all meant handling those literatures as a single subject, which disciplinary training rarely does. Paper X derived, in a minimal model of recursive self-improvement, an exponent criterion for a vanishing misalignment fraction (correction that out-scales drift), whose central move, refusing to treat capability and correction as separable, cuts against the field's default decomposition. None of this demonstrates that neurodivergent cognition is necessary for such work, and none of it compares institutional composition with the individual route as a cause of the findings. It shows that the work came from outside the field's institutions, on documented dates; that the field's 2026 results about artificial agents bear on that pattern is the bridge this section states as a hypothesis.

The implication for institutions is uncomfortable and practical: exclusion of atypical cognitive profiles from research, funding and legal participation is an equity failure and, if the bridge holds, a technical risk as well. The Capability-Adjustment Fallacy, operating in hiring committees, grant panels and courtrooms, is one of the mechanisms by which that exclusion happens.

10 Operationalisation and falsifiability

For the construct to be scientifically serious rather than self-descriptive, it must be operationalised and exposed to refutation.

Measurable components. PNP would be indicated by: (a) documented cross-domain output over time; (b) evidence of self-directed learning; (c) demonstrable pattern transfer between fields; (d) a measurable asymmetry between performance on preferred, high-interest versus non-preferred, low-stimulation tasks; (e) clinical evidence of executive-function impairment in routine administration; and (f) evidence of institutional under-recognition, where outputs and impairments are treated as mutually inconsistent.

Conditions under which PNP should be abandoned. The hypothesis fails if it cannot be reliably distinguished from (i) ordinary high openness to experience, (ii) ordinary giftedness, (iii) narcissistic or grandiose self-description, or (iv) general executive dysfunction; or if naming it adds no predictive or practical value beyond existing autism and ADHD formulations. These are real tests, and the paper welcomes them. The decisive empirical question is whether PNP *incrementally* predicts the preferred versus non-preferred task asymmetry and the institutional under-recognition outcome beyond what existing instruments already capture. If a validated measure showed PNP variance collapsing into those existing constructs, the construct should be discarded, and this paper's own falsification register commits to saying so publicly.

Research questions. Can clinicians and researchers reliably identify a cross-domain strengths-and-needs profile? How often does it appear among autistic and ADHD adults with histories of self-directed expertise? Does naming it improve clinical reporting, workplace support, educational accommodation, or court participation? The documented case in Section 7 supplies a template for the documentation standard such research would need: separately kept record streams rather than self-report alone.

Standing covenant. Prove this paper wrong, and I will publish the refutation myself. Falsification conditions are stated in this paper; the standing challenge: github.com/MichaelDariusEastwood/arc-scaling-challenge.

11 Clinical relevance: what a report can legitimately say

The clinically defensible request is **not** that a psychiatrist diagnose "polymathy". It is that the psychiatrist provide a full adult autism assessment and, if clinically justified, describe the person's strengths, support needs, thinking style, executive-function profile, and functional consequences in real settings. That is consistent with NHS and NICE reporting principles and with neuro-affirming practice (NICE 2021; NAIT 2024).

A report could properly state, in substance, that the individual presents with autism-spectrum features and ADHD-related executive-function difficulties, together with an unusually strong profile of self-directed learning, pattern recognition, cross-domain synthesis, and productivity in selected high-interest domains; and that the *same* neurodevelopmental profile produces marked functional disadvantage in routine administration, timekeeping, task-switching, and low-stimulation procedural work. The clinically important addition is the explicit statement that **the asymmetry itself is the finding**: high-level output should not be read as evidence that support needs are absent.

This formulation is more powerful than grand claims precisely because it remains sober, observable, and demand-specific. It asks the clinician to explain functioning, not to certify genius or legal correctness.

12 Legal relevance: adjustments restore equal footing; they do not confer advantage

The court-facing formulation should be precise and restrained, and should ask the court only to act consistently with its own access-to-justice obligations and with the functional evidence in any diagnostic report.

The statutory architecture supports this directly. The Equality Act 2010 imposes a duty to make reasonable adjustments where a provision, criterion, or practice places a disabled person at a substantial disadvantage (s.20), and in the exercise of public functions that duty is anticipatory. The Public Sector Equality Duty requires due regard to advancing equality of opportunity (s.149), and s.149(6) expressly provides that compliance "may involve treating some persons more favourably than others": statutory authority that adjustment is not unfair advantage. In civil litigation, CPR 1.1 and Practice Direction 1A require the court, so far as practicable, to ensure that parties are on an **equal footing**, can **participate fully**, and can give their **best evidence**, and recognise that vulnerability, including mental impairment or disability, may both impede participation and diminish the quality of evidence (CPR PD1A 2021).

Within that architecture, the Capability-Adjustment Fallacy has a precise legal form: it substitutes a global impression of ability for the statutory question, which is always demand-specific disadvantage. A tribunal that reasons "this litigant writes able submissions, therefore no substantial disadvantage arises from these deadlines, this correspondence load, this hearing format" has answered a question the statute does not ask, and left unanswered the one it does. The correct sequence is the functional one set out in Section 5: identify the demand, identify the disadvantage on the evidence, identify the adjustment, and test it against fairness to the other parties. Nothing in that sequence turns on how clever the person's best work looks.

13 Limitations

Single-case evidence. Section 7 documents one instance, however thoroughly. A documented case can instantiate a construct and refute the claim that no such profile exists; it cannot establish prevalence, and it cannot by itself validate the construct. The paper's population-level claims rest on the cited literatures, not on the case.

The case is the construct's source. The profile was named from the documented case, so the case illustrates the construct rather than testing it, and its subject is also its assessor. Abandonment condition (iii) of Section 10 cannot be settled by this case; a test needs cases identified by others against criteria fixed beforehand, which is the study Section 10 commits the construct to.

What would change this paper. A validated instrument showing PNP variance fully absorbed by existing constructs; adult-population studies contradicting the asymmetry pattern; or failures of the documentation standard in Section 7 under qualified scrutiny. Any of these would be recorded on the programme's public falsification register.

13.1 Ethics statement

Author as subject. The author is the documented case, which creates an obvious interest. Three mitigations are structural rather than rhetorical: the evidence streams are records kept for other purposes, two of them by institutions, none authored for this paper; the falsifiability conditions in Section 10 are pre-committed and public; and the research programme this paper belongs to has already retracted one of

its own quantitative claims when replication failed, with the retraction kept on the public record. Readers should nonetheless weight the case study as what it is: an unusually well-documented n of 1.

Privacy and dignity. Publishing one's own diagnostic status invites both stigma and its mirror image, inspiration narrative. The paper intends neither. The clinical stream is disclosed at the minimum level of detail the argument requires; the clinical documents themselves remain private. No inference should be drawn from this paper about any other person's profile, and the profile itself, as Section 2 states, confers no superiority: its costs are clinical, documented, and lifelong.

Live litigation. The court record is cited as an instance of a documented asymmetry, not as commentary on the merits of any proceedings, which remain for the courts that hear them.

14 Conclusion

The Polymathic Neurodivergent Profile is offered as a working hypothesis, not an established finding. It is falsifiable, it is open to correction, and it makes no claim to diagnostic status. It is a descriptive framework for a pattern it argues is real, institutionally consequential and systematically misread; and it now has something such frameworks rarely have: a documented live case across separately kept clinical, legal and dated research records, and a 2026 literature in AI alignment, from formal logic to PNAS Nexus, on the limits of verification and on diversity among artificial agents, which this paper reads, by a bridge it states as a hypothesis (Section 9), as bearing on its central implication that cognitive diversity is not a concession but a resource.

The Capability-Adjustment Fallacy, the inference that visible high performance is evidence that adjustments are unnecessary, is unsafe. It is contradicted by clinical guidance, incompatible with the statutory architecture of the Equality Act 2010 and CPR PD1A, and, if the bridge of Section 9 holds, technically costly to a research problem that can ill afford shared blind spots. The correction is not special treatment. It is the recognition that capability in one domain does not remove support needs in another, and that the same cognitive architecture which produces extraordinary output in favoured domains may be unable to produce consistent output in routine ones without structural accommodation.

The researcher who wrote this paper is the case study. The manuscript hashes are published. The court record exists. The clinical documentation exists. The convergence register is public, with priority credited to others wherever the dates demand it. The question this paper leaves with its readers is the one the fallacy prevents institutions from asking: not "how capable does this person seem?" but "what does this specific demand cost this specific mind, and what would fairness actually require?"

Acknowledgements

Michael Darius Eastwood conceived and directs this research programme and is the author of this work. Across the programme, he has used more than six AI systems in parallel, under his own instructions, to stress-test his arguments, identify possible errors, and assist in preparing draft text from his own outlines. He determines what is adopted, revised or rejected and takes responsibility for the published content. These systems are tools, not authors.

A Version history and corrections

Every version and correction, with its date. Notes and entries from earlier versions are kept as printed.

A.1 Version 1.11

Paper C v1.11, 29 October 2026. This version sets the paper in LaTeX to the programme's presentation standard. The sections are renumbered from 1, and Table 3 gives where each part of version 1.10 now stands: the three background sections form Section 3; the definition, the mechanism and the retrospective literature form Section 4; the working-status statement, the reading key and the epistemic-status line join the claims boundary in Section 2; the contributions join the introduction; and the standing covenant closes Section 10. The title is now the paper's question, and the OSF record keeps its title. The abstract is shortened to at most 1,920 characters, and each of its earlier sentences stands in the body; the keywords are carried in the document's metadata. The corrections made in this version are these. (i) Laws IV and V are stated as registered as laws on 15 October 2026 in version 1.103 of the theory registration, and their mathematics is cited at version 1.1 of 7 October 2026. The epistemic-status line had said that the predictions carrying the two laws were registered but the laws themselves were not, and that Laws I to III were under registered adversarial test; the note of 3 October 2026 on this paper and Laws IV and V had said that neither law was registered as a law, and had cited the mathematics at version 1.0 of 3 October 2026. The status line also states each law's status, with P21's counted test, Unit 83, and its result, public since 29 October 2026 (results DOI 10.17605/OSF.IO/98HKR), and the programme's first registered study, Unit 06. (ii) The time of the record of 8 December 2024 is stated by who signed it, the mail servers, in Section 7.3 and in its provenance note of 19 September 2026 (now in Appendix A.5), where both, like the abstract, had set the provider's assertion against a time-stamping authority's token; the note's other words are unchanged. (iii) Paper IV.d's finding is given in its own terms: on the programme's own benchmark, two model families' unblinded rises did not hold in a later run that changed several things, a bundle of blinding steps among them, and no single cause is claimed. Section 7.3 had said that unblinding reversed the sign of a result, and Section 9 that the direction changed once scoring was blinded; the sentence after it in Section 9, on unblinded scoring across the field, is now conditional on such results holding. (iv) Paper X's result is given in its own terms, an exponent criterion for a vanishing misalignment fraction proved inside a minimal model, where Section 7.3 had said that the condition was demonstrated so far only in simulation and Section 9 had called it a stability condition for recursive self-improvement. (v) The paragraph on the author's first theory, now in Section 7.3, names the HRIH monograph as such and keeps it apart from the programme's tested claims; it had said that HRIH states the hypothesis and that Papers I to XI operationalise it. (vi) The scope note of 19 September 2026, now in Appendix A.5, reads the step from the result about artificial agents to human institutional composition as a bridge stated as a hypothesis, where it had called it a bridge put forward and not validated; its other words are unchanged. (vii) References: the NICE guideline gives its first publication, 27 June 2012, and its last update, 14 June 2021, where it read 2021, updated 2025; the James entry links the publisher's catalogue page, which lists the ebook edition, where it said that the catalogue did not list the book; the Gumbau Mezquita entry, which cites its first version, records the new title of its fourth version of 14 October 2026; the book is linked to its first edition as printed, deposited on OSF; the mathematics of Laws IV and V is linked to its DOI; and the reading key names the section and version of the Eden Protocol's philosophical statement it points to, linked to its DOI. (viii) The first-page footnote gives the paper's place and links the page on who the author is and his book; the copyright line carries the author's standard wording, where it had also cited United States Copyright Office guidance and the authorship statement on the author's website.

This version also makes the following corrections. (ix) The three documentation streams of Section 7 are described as separately kept, by parties with no common interest and no coordination, where the

abstract, the introduction, the claims of Section 2, Section 7, the research questions of Section 10, the ethics statement and the conclusion had called them independent, the case fully documented or the records institutional; Section 7.3 now says in its text what its provenance note said, that the third stream attests dates and byte integrity, not the asymmetry, and that whether its domains are distinct and its transfer substantive is a matter for assessment against stated criteria. (x) Sections 8, 9 and 14 now say in their text what the reading and scope notes of 19 September 2026 said: no citation of, or connection to, the author's work by either group has been identified, which is weaker than showing that neither knew of it; Hernández-Espinosa et al. write about artificial agents, and the human-cognition reading is this paper's own; the formal result is relevant to the control-failure half of the manuscripts of 8 December 2024 under its own assumptions and does not establish their remedy; and the step from artificial agents to the composition of the research field is a bridge stated as a hypothesis. Section 8 had described their paper as arguing that neurodivergent cognition protects alignment research, and the formal result as a proof that vindicated the author's thesis; Section 9, that the field's 2026 results now predict the pattern and that exclusion is a technical risk; and the conclusion, that an independent 2026 literature converges on the paper's central implication. (xi) Prior work is stated as it reads. Section 3.3 cites the systematic review it mentions, Rizzo et al. (2025), keeps to its words and gives the point to Silverman, as the review does, and states with that review that gifts and difficulties can mask each other, so that such learners' needs may go unrecognised; Section 4.1 no longer says that the twice-exceptionality literature is silent about what follows institutionally. Section 4.3 gives the trait-patterns the retrospective analyses report, and systemising as the genetic study measured it, where it had said that they keep finding the same trait-cluster and spoke of cross-domain analytical pursuit; and the Sharma and Chopra and Baron-Cohen entries in the references carry bibliographic facts only. (xii) Claims are stated at the size of their evidence. Table 1's evidence grades follow the text; the claims of Section 2 give as an expectation, which Section 10 sets as a research question, what they had stated as settled; the employment outcomes of Section 6.2 are said to be consistent with capability going unrecognised, and the position on generative AI is given as this paper's; the hypothesis of Section 4.2 is stated as untested, the claim that the comparison was the ARC Equation's to make as the author's reading, and the vignette no longer calls the author's wife linear-thinking or says why specialists were unlikely to have produced cross-domain work; the case record of Section 7 names the asymmetry the profile names, where it had said that the profile predicts it; Table 2 calls the record of 8 December 2024 dated, not public, and gives each anchor its identifier; Section 7.3 no longer prints the ungraded count of 2 July 2026 beside the convergences, which it had called independently sourced, and calls the audit's analysis preregistered, not registered; and the incremental-validity study is named as Unit 64, with its later anchor. (xiii) NICE CG142 is quoted from its recommendation 1.1.3 as that recommendation reads, and the abstract keeps its word "potential". (xiv) The introduction's paragraph on the author's first theory now stands in Section 7.3, whose evidence it is; it no longer calls the derivation chain timestamped end to end, the case the cleanest possible exhibit or the theory the profile's product, and it names cosmology and theology last. The reading key says what section II.A.8 of the Eden Protocol's philosophical statement sets out. A limitation is added to Section 13: the case is the construct's source. Appendix A.5 quotes every passage restated in this version as version 1.10 printed it, and holds the three notes of 19 September 2026, which no longer stand beside the passages they qualified, since those passages now say what the notes said. (xv) Editorial: the secondary line gives the paper's category and its signed programme line; the contributions cite by author and year; a printed DOI no longer breaks with a hyphen; the reference list keeps its proper names' capitals, adds Rizzo et al. (2025), the fifth edition of the DSM (American Psychiatric Association 2013) and Unit 83's results, and names the OSF components that hold the record of 8 December 2024 and the priority index; the remaining mentions of cited works are linked; three marks of punctuation follow British usage; and the appendix tables are set so that each stands under its heading. No registered law, prediction, kill condition or dependency changes, and no date of any claim moves; the one result added is Unit 83's, in Section 2.

A.2 The note of 3 October 2026, as printed

The note and the entries below are kept as printed, newest first. Their section numbers are those of the version each describes; Table 3 gives where each section now stands.

Note (3 October 2026): what ten corrected passages and three note headings printed before. *The working-status box at the head of this paper said that no claim in it was on trial through a programme draft study. The incremental-validity test that section 12 sets out is drafted as a programme follow-on study and preregistered by timestamp, so the box now gives that state, and the reading key adds it. In section 6A, the quotation from the book's Author's Note left out two words of its first sentence, the name of a framework, and now gives the sentence as the book prints it. The same section said that the field had demonstrated that sequential, iterative, self-questioning reasoning outperforms parallel sampling on the same problems, and its hypothesis spoke of the reasoning architecture the field had just proved superior. Both passages now state Sharma and Chopra's result in their own verb: they find that sequential scaling outperforms parallel self-consistency at matched compute in 95.6% of the configurations they evaluated. In section 9, the account of the third stream described its co-scaling stability condition as having a first real-model demonstration. Paper X withdraws its real-model drift run of 2 July 2026 as mechanism evidence and states that the condition is demonstrated only in simulation, with its measurement on real systems unsolved, and the passage now says so. The same account said that no programme draft study covers the convergence. The programme's audit of how many of the convergences are independent is a draft study, preregistered by timestamp, and the account now gives its state. The evidence box that follows said that the same structure was applied to quantum error correction, metabolic scaling and reinforcement-learning drift years before independent groups published parallel structures in each domain; that clause is withdrawn, and the box now says that each application is dated. In section 11, the exploratory-analysis marker said that none of this paper's own quantitative content is tested by a programme draft study. The test of section 12 is drafted as such a study, so the marker says instead that none of that content has yet been tested. The same section said that Paper IV.d showed that unblinded AI evaluation can reverse the sign of an alignment result; it now gives Paper IV.d's own finding, that for two model families the direction of the alignment-depth relationship changed once scoring was blinded. The epistemic-status line said that what the programme names Laws are conjectures under registered adversarial test; it now gives Laws I to III and Laws IV and V their separate status. The headings of the three notes of 19 September 2026, in sections 9, 10 and 11, said that each note was added after an owner review; they now give the date without that clause. Unchanged: every other claim, date and limit of this paper, and the text of its three notes of 19 September 2026.*

A.3 Earlier versions, as printed

Paper C v1.10 - 5 October 2026: the title now follows the programme's uniform order (paper, its law or framework, its own title), *Paper C · Standalone · Polymathy and Neurodivergent Cognition: the Polymathic Neurodivergent Profile (PNP) and the Capability-Adjustment Fallacy*; until this version it read *Polymathy and Neurodivergent Cognition: the Polymathic Neurodivergent Profile (PNP) and the Capability-Adjustment Fallacy*, under the heading *Polymathy and Neurodivergent Cognition*. Mentions of the programme's papers in this paper now carry their uniform titles. No registered law, prediction, kill condition or dependency changes; no result is added; no date of any claim moves.

Paper C v1.9 - 3 October 2026: ten passages are corrected where they stand, and a dated note before the references records what each printed before. The working-status box said that no claim in the paper was on trial through a programme draft study; the incremental-validity test of section 12 is drafted as a programme follow-on study, preregistered by timestamp and awaiting human submission, and the box and

the reading key now say so. In section 6A, the quotation from the book's Author's Note now gives its first sentence whole, as the book prints it. The same section and its hypothesis now state Sharma and Chopra's result in their own verb, that they find sequential scaling outperforms parallel self-consistency at matched compute, where they said that the field had demonstrated and proved it. In section 9, the third stream's scaling-theory work no longer carries a first real-model demonstration: Paper X withdraws its real-model drift run of 2 July 2026 as mechanism evidence and states that its condition is demonstrated only in simulation. Section 9 also said that no programme draft study covers the convergence; the programme's audit of how many of the convergences are independent is a draft study, preregistered by timestamp, and the section now gives its state. The evidence box in section 9 no longer says that the corpus applied its structure years before independent groups published parallel structures in each domain; it says that each application is dated. In section 11, the exploratory-analysis marker now says that none of this paper's own quantitative content has yet been tested, where it said that none is tested by a programme draft study, and the sentence on Paper IV.d gives its own finding, that for two model families the direction of the alignment-depth relationship changed once scoring was blinded, where it said that unblinded evaluation can reverse the sign of an alignment result. The epistemic-status line now gives Laws I to III and Laws IV and V their separate status. The headings of the three notes of 19 September 2026 no longer say how the notes came to be added; their dates and text are unchanged. A dated note in section 10 states how this paper stands to Laws IV and V: the paper reports what the manuscripts of 8 December 2024 state about embedded correction, and it tests neither law. The abstract now says that the paper sets out the Polymathic Neurodivergent Profile, and section 6 that the profile is a descriptive construct stated as a hypothesis; both said that it was proposed. Twelve reference entries are corrected from their official records: the Araki entry printed a DOI registered to another article and now gives the one Crossref registers for it, which no longer leads to the journal, with the issue as Crossref gives it; five titles printed in short form are given in full; the NAIT guidance, the DeepSeek-R1 report and the Warrier author list follow their own records, the NAIT entry with the authors its own citation names and the DeepSeek-R1 entry with the date of its first arXiv version; the James entry no longer presents a bookseller's page as the publisher's record, since the publisher's catalogue does not list the book; the Baron-Cohen entry gives the ISBN that the publisher's page shows; and the Fitzgerald entry, with its mention in section 6B, gives the imprint its record names. Ten works cited in the text and missing from the references are added from their official records: Part 1 and Practice Direction 1A of the Civil Procedure Rules, the Equality Act 2010, the NHS page on autism assessments, and six of the author's own works, Papers I, III and XI, the HRIH paper, the Eden Protocol's philosophical vision and the report on the mathematics of Laws IV and V. The works the paper cites are linked to their official sources where one can be reached, and each of the author's own papers to its DOI. Substantive: the ten corrected passages and the note on Laws IV and V. Editorial: the headings of the three dated notes, the verb in the abstract and section 6, the references, the links, the dateline, the footer and the page's structured and citation records, which carry the new version and date. No registered law, prediction, kill condition or dependency changes; no result is added; no date of any claim moves.

Paper C v1.8 - 21 September 2026: three dated notes are added beside passages that already stood, and no sentence of the paper is changed. In section 9, a provenance note below the third-stream evidence box separates what a carrier establishes, the integrity of the signed bytes as sent and a carriage time asserted on the signing domain's authority, from what assessment of the documents against stated criteria establishes, and carries the same limit into the paragraph on the three streams below it. In section 10, a reading note below the three points of precision states that a public record evidences the absence of an identified citation or connection rather than the absence of knowledge, that the external preprint's subject is artificial agents exactly as the table above it already says, and that the 2026 formal results are relevant to the control-failure half of the 8 December 2024 content under their own stated assumptions rather than establishing it. In section 11, a scope note below the institutional conclusion carries the conditional at the head of that section and the necessity limit already printed above it into the conclusion, and reads

the step from a diversity result about artificial agents to a claim about human institutional composition as a proposed bridge rather than a validated implication. All three are substantive qualifications of how existing passages are to be read, and none is editorial. No claim is withdrawn and no recorded date, result or status changes; the revision dateline and the version fields move with the version, as they do at every revision. Each note keeps the 19 September 2026 label of the frozen owner-decision text it reproduces, preserved unchanged as that file's own historical label; the owner decision that settled the three notes is dated 20 September 2026, and this revision is published on 21 September 2026. The date of first publication, 3 July 2026, is unchanged.

v1.7: The provenance note at the end has been corrected for accuracy. No claim, date, result or status has changed.

Paper C v1.6 - 2 September 2026: in the cognitive-monoculture section the cross-domain mapping now credits the Foundational paper rather than Paper III, and the Foundational paper joins the reference list; the third evidence stream states its convergence under the register's no-total policy, keeping the nineteen as the dated snapshot of 2 July 2026; Cage and Troxell-Whitman (2019) and DeepSeek-AI (2025) are cited in the running text as well as listed; Paper X appears under the title it now bears; the citation block carries this paper's own DOI (10.17605/OSF.IO/RBHDP) in place of the programme umbrella; a structured-data link pointing to another author's preprint is gone; the footer version matches the version shown on the first page.

Scope note of 19 September 2026, section 11	Appendix A.5

A.5 Passages restated in version 1.11, and the three notes of 19 September 2026, as printed

Version 1.11 restates where they stand the passages quoted below (Appendix A.1, items (ix) to (xiv)). Each is quoted as version 1.10 printed it, under the section number it had there; Table 3 gives where each section of version 1.10 now stands. The three notes of 19 September 2026 follow, as this version prints them; their words "above", "below" and "the next paragraph" refer to the places they stood in sections 9, 10 and 11 of version 1.10, now Sections 7, 8 and 9.

Abstract. "NICE CG142 already directs professionals to recognise the discrepancy between intellectual functioning and adaptive functioning"; "evidenced across three independent documentation streams".

Contributions of this paper, the fourth. "A convergence analysis connecting the profile to independent results in AI alignment: agent diversity as a counterbalance under a neurodivergence analogy (PNAS Nexus, 2026) and the structural insufficiency of external verification (arXiv:2606.28639), with a precise, timestamp-anchored account of what preceded what."

Section 1. "The paper goes further than naming the pattern: it documents a live instance across three independent record types, and it situates the pattern inside a set of 2026 results in AI alignment that have made cognitive diversity a research question rather than a slogan."

Section 1, the paragraph now in Section 7.3. "One biographical fact orients everything that follows. The documented case of Section 9 did not begin as an AI-safety researcher: he began as a creation theorist. The December 2024 manuscripts are, before anything else, a theory of why created systems persist: recursion amplifies, and only embedded, co-scaling correction prevents amplification from becoming destruction. The AI-safety programme, the scaling-law papers, the stability criterion and the book all derive from that single creation-theoretic move, and the derivation chain is timestamped end to end (HRIH states the hypothesis; Papers I to XI operationalise it). This matters for the present paper because it is the cleanest possible exhibit of PNP component 2, recursive pattern transfer: one structural idea, extracted once, applied across theology, cosmology, error correction, biology and machine learning, on checkable dates. The profile did not produce scattered interests; it produced one theory with many testable faces."

Section 2. "It claims: that there exists a recurring, describable pattern of cross-domain high ability combined with disability-linked impairment in routine procedural functioning; that this pattern is currently under-described by deficit-only and credential-centric models; that describing it improves the accuracy of clinical formulation and the fairness of institutional treatment; that the supporting components are individually grounded in existing literature; and that one fully documented instance exists whose records are open to qualified scrutiny."

Reading key. "This paper documents a PROFILE, not a theory: the Polymathic Neurodivergent Profile and the Capability-Adjustment Fallacy as an analytical construct sitting alongside the theory's organs rather than inside them. §12's incremental-validity check is drafted as the intended future evaluation, preregistered by timestamp and awaiting human submission, and every quantitative first-mention is labelled exploratory." Its last sentence pointed to section II.A.8 of the Eden Protocol's philosophical statement as the full differential against every prior document.

Section 4. "Together these accounts predict exactly the signature PNP describes: sustained, high-output engagement with self-directed, high-interest, high-complexity material, and disproportionate difficulty with externally paced, low-stimulation, low-reward procedural tasks."

Section 5, on asynchrony. "A recent systematic review notes that asynchrony intensifies precisely when high intelligence coexists with significant weakness."

Section 5, on the social consequence. "The literature also names the social consequence PNP is concerned with: such individuals can be too able to be seen as disabled, and too disabled to be recognised as able, and are therefore frequently misread by systems that expect ability to be uniform."

Section 6, the evidence grades of the profile's table. Component 2: "STRONG mechanism literature; profile-level evidence observational". Component 4: "STRONG (Ashinoff and Abu-Akel, 2021; Russell et al., 2019)". Component 5: "STRONG (NICE CG142 IQ-adaptive gap; Hill, 2004; Demetriou et al., 2018)". Component 6: "STRONG (underemployment, masking and burnout literature; Buckland, 2024; ONS, 2021)".

Section 6, on twice-exceptionality. "Twice-exceptionality pairs general giftedness with a co-occurring disability, is overwhelmingly a child-and-education construct, and is silent about what follows institutionally."

Section 6A, on the mechanism. "Section 4 describes this pattern from the outside as monotropism; this subsection describes it from the inside." "It is a wiring, and a costly one, whose costs are the executive-function impairments recorded in §5 and evidenced across the case in §9."

Section 6A, on the convergence. "The convergence is the sharpest new point in this subsection."

Section 6A, on credit. "The standing three-layer crediting discipline applies here without exception." "The 8 December 2024 timestamp anchors a one-sided directional statement, not the comparison; the comparison was nonetheless the equation's to make, since parallel width has no term in $U = I \times R^{\alpha}$, and that derivation was completed in 2026 by the operational definition of R, carrying the date of its youngest premise."

Section 6A, the hypothesis. "In reasoning-token architectures that make chain-of-thought visible at scale, the field is engineering into machines the iterate-question-iterate loop a monotropic mind already runs natively." "HYPOTHESIS The neurodivergent cognitive style documented in this paper may be the biological instance of the reasoning architecture that Sharma and Chopra find outperforms parallel self-consistency. If the hypothesis holds, it would explain both the polymathy (compounding cross-domain training) and the priority record recorded in §10: the loop was running in a single mind for years before the machines had it."

Section 6A, the vignette. "A linear-thinking professional (the author's wife, a dentist) once agreed to role-play a student of the cross-domain framework." "Cross-domain work has no home discipline, which is precisely why single-domain credentialled specialists were unlikely to have produced it, and why the Capability-Adjustment Fallacy's institutional home, 'which box does this person fit?', is the same question in another costume."

Section 6B, its first safety rule. "PNP itself takes no support from any individual retrospective case; the paper's interest in this literature is the pattern that credentialled retrospective analyses keep finding the same trait-cluster in history's cross-domain synthesisers."

Section 6B, on systemising. "Baron-Cohen's hypersystemising theory identifies the drive to detect if-and-then causal patterns as one of the engines of invention and cross-domain analytical pursuit".

Section 6B, on the genetic correlation. "It does place the systemising drive characterising cross-domain analytical pursuit on a genetic axis linked to autism at the population level, rather than a purely biographical curiosity, and it is the kind of finding a reader can check."

Section 6B, the hypothesis. "HYPOTHESIS The connection between the trait-cluster that credentialled retrospective analyses keep finding in history's cross-domain synthesisers, and the profile named in §6, is a hypothesis, not an established finding."

Section 6B, its closing tie. "The closing tie is short. The book from which this paper descends (Eastwood, *Infinite Architects*, 2026a) chose Rumi, Teilhard de Chardin and Leibniz as its exemplars in the Introduction. The choice was principled, not decorative: those three were selected precisely because they were documented cross-domain synthesisers, and because the polymathic method (§6A closing block) is what they had in common. This subsection is that principle stated more carefully. The individual figures remain the property of the retrospective literature that examines them; the method is what is claimed, and it is claimed as method, not as stature."

Section 7. "NICE CG142 directs all health and social care professionals to understand 'the potential discrepancy between intellectual functioning as measured by IQ and adaptive functioning as reflected, for example, by difficulties in planning and performing activities of daily living including education or employment' (NICE, 2021)."

Section 8, employment. "Capability is plainly not being converted into recognition."

Section 8, artificial intelligence. "Generative AI can accelerate drafting, research, and synthesis, but it does not originate the judgement, selection, cross-domain integration, and strategic direction that decide what to do with that output."

Section 9, its heading. "A documented live case: three independent evidence streams".

Section 9, its opening. "This paper can do something unusual: present a single, fully documented instance in which the profile and the fallacy are recorded in three independent documentation streams, generated by different institutions for different purposes, none of them constructed for this paper. The subject is the author."

Section 9, the clinical record. "The author holds adulthood diagnoses of autism spectrum condition and ADHD, with independent psychiatric documentation describing precisely the asymmetry the profile predicts".

Section 9, the court record. "The record of that litigation contains, simultaneously: substantive written work of a standard the opposing parties engaged specialist counsel to answer, and repeated applications for modest procedural adjustments under the Equality Act 2010 and CPR PD1A, disclosed disability, and documented difficulty with exactly the procedural demand classes the profile predicts (deadlines, sequencing, administrative correspondence)." "The paper takes no position here on the merits of any live proceedings; the record is cited only as a documented instance of the demand-specific asymmetry, and it is a matter of court record rather than self-report."

Section 9, the research corpus. "Independently sourced external events have since converged on the corpus's structural claims;" and, in the same sentence, "(a snapshot retained from before the grading, dated 2 July 2026, put the number at nineteen, an exploratory count kept for reference;" and "its data already exist, and its registered analysis has not been run".

Section 9, the evidence box. "A hash-timestamped corpus solves both problems. The dates cannot be backfilled, the domains are objectively distinct, and the transfer is inspectable in the documents themselves: the same recursion-and-correction structure is applied to quantum error correction, metabolic scaling, and reinforcement-learning drift, with each application dated. Whatever one thinks of the corpus's conclusions, its existence, dates and breadth are checkable facts, and they are exactly the facts the profile predicts and the credential system failed to register."

Section 9, its closing paragraph. "The three streams are independent in the relevant sense: a psychiatrist, a court, and a mail server have no common interest and no coordination. Their agreement on the same asymmetry, high structured output here, impaired procedural functioning there, is the strongest form of documentation available for a single case, and it converts the profile from an introspective claim into an auditable one."

Section 10, its opening. "The framework's position in time can be recorded precisely, because 2026 produced independent results that bear directly on its central claim."

Section 10, the chain's table. Its first row: "the corpus that instantiates PNP components 1 to 4 begins its public timestamp record"; its last row's anchor: "This paper; OSF".

Section 10, the three points of precision. "Second, no causal claim is made in either direction: neither group had any way to know of the author's work, and that mutual ignorance is what gives the convergence its evidential value. Third, the chain has a striking internal structure: a paper arguing that neurodivergent cognition protects alignment research from shared blind spots served as the stated foundation for the theorem that formalised what a neurodivergent researcher had argued structurally eighteen months earlier. The paper about minds like the author's inspired the proof that vindicated the author's thesis. The chain is documented end to end; every link is independently checkable."

Section 11, its opening. "The convergence chain points at a field-level implication that goes beyond any single person. If Hernández-Espinosa and colleagues are right that uniform compliance cannot deliver alignment and that behavioural diversity is protective, then the composition of the research field itself becomes a safety variable. Uniform minds, trained in the same institutions on the same curricula, tend to miss the same things in the same direction at the same time. That is a monoculture risk, and it is invisible from inside the monoculture."

Section 11, the three instances. "One recursive-amplification structure runs through quantum error correction, biological scaling and machine reasoning, and the Foundational paper set it out; drawing that map at all meant handling those literatures as a single subject, which is exactly what disciplinary training discourages." "None of this demonstrates that neurodivergent cognition is necessary for such work. It demonstrates that the work in fact came from outside the monoculture, on documented dates, and that the field's own 2026 results now predict exactly that pattern."

Section 11, the implication for institutions. "The implication for institutions is uncomfortable and practical: exclusion of atypical cognitive profiles from research, funding and legal participation is not only an equity failure. On the field's own emerging evidence, it is a technical risk."

Section 12, the research questions. "The documented case in Section 9 supplies a template for the documentation standard such research would need: independent record streams rather than self-report alone."

Section 15, the ethics statement. "Three mitigations are structural rather than rhetorical: the evidence streams are institutional records not authored for this paper;".

Section 16, its first paragraph. "It is a descriptive framework for a pattern that is real, institutionally consequential, and systematically misread; and it now has something such frameworks rarely have: a fully documented live case across independent clinical, legal and cryptographic records, and an independent 2026 literature, from formal logic to PNAS Nexus, converging on its central implication that cognitive diversity is not a concession but a resource."

Section 16, its second paragraph. "and on the field's own emerging evidence, technically costly to the one research problem that can least afford shared blind spots."

References. The Baron-Cohen entry ended "Developed from a longer research programme on empathy and systemising in autism, hypersystemising as an engine of cross-domain analytical pursuit." The Sharma and Chopra entry ended "arXiv:2511.02309, 4 November 2025. Independent quantification of the sequential-over-parallel finding; publication priority on the quantified number credited unreservedly per the three-layer discipline."

Provenance note (19 September 2026): what the carrier establishes, and what reading establishes. *A domain signature over a message establishes the integrity of the signed bytes as sent, and asserts a carriage time on the signing domain's authority. It does not establish semantic merit, originality, causal origin or construct validity, because none of those is a function of the bytes and the signing time alone. The two properties the paragraph above relies on, that the domains are objectively distinct and that the transfer is inspectable in the documents themselves, are matters for assessment of the documents against stated criteria; the hash and the signature do not deliver them, and reading alone does not settle a substantive cross-domain transfer without those criteria and an assessor applying them. "The dates cannot be backfilled" is read at the strength this paper states earlier: the signature-time assertion is a time signed by the mail servers, Google's among them, so it is a trusted-third-party assertion, and the sender controls both the content and the moment of sending. The same limit governs the next paragraph: the third stream attests carriage and byte integrity, not the asymmetry, which is a property of the content assessed against criteria. Unchanged: the existence, dates and breadth of the corpus as checkable facts; this paper's earlier and governing statement of the carrier's status; and the agreement of the first two streams.*

Reading note (19 September 2026), governing the three points of precision above. *First, what a public record evidences is the absence of any identified citation or connection, which is weaker than the absence of knowledge; a universal negative about what other people knew is not established by a record of what was published. Second, the external preprint's subject is artificial agents, and the human-cognition reading is this paper's own claim and never theirs, exactly as the table above states; the shorter phrase in the paragraph above is read against that table, which governs. Third, the 2026 formal results are an unverifiability theorem and a soundness, completeness and tractability trilemma. A limit on universal verification is relevant to the control-failure half of the 8 December 2024 content under the theorem's own stated assumptions. It does not establish the embedded-correction remedy, because a limit on verification says nothing about whether embedding correction is the remedy; and it does not by itself establish the whole of the control-failure half either, since that would need the theorem's assumptions and the claim's content compared term by term, which the paragraph above does not do. "Vindicated" is therefore read as relevance to the first half under stated assumptions, and not as establishment of either half. Unchanged: the dates and the direction of every gap; the disclaimer earlier in this paper that no external research result is claimed to have been caused by the author's cognition; and the table's own scope statement.*

Scope note, added 19 September 2026: the conclusion above states a consequent, and is read with its antecedent in place. *The claim at the head of this section is printed in conditional form, and the conclusion above inherits that condition. "On the field's own emerging evidence" identifies where the evidence comes from; it does not restore the conditional and it does not supply a comparison. The necessity limit printed above governs here too: this paper states that none of this demonstrates that neurodivergent cognition is necessary for such work. These passages also do not supply a comparison that would establish institutional composition, rather than the documented individual route, as the cause of the findings, so the step from the diversity result about artificial agents to a claim about human institutional composition is read as a bridge stated as a hypothesis and not as a validated implication. Unchanged: the conditional statement at the head of this section; the exploratory-analysis marker and the necessity limit above, both of which are already printed and both of which govern; and the account of the Capability-Adjustment Fallacy in the paragraph above.*

B Priority record

Each dated record bearing on this paper, with its kind of timestamp (Table 4). The external events of the convergence chain carry their own anchors in Table 2. The programme's priority index, a working draft, gives the earliest dated record of each of the author's major claims.

Table 4. The paper's dated records, each with its identifier and the kind of timestamp that dates it; the external events of the convergence chain are in Table 2.

Date	Record	Identifier	Kind of timestamp
8 December 2024	The self-emailed manuscript bundle, roughly 221,236 words (Section 7.3): the control-failure thesis for AI alignment, the embedded-correction remedy, and the one-sided directional statement that recursion amplifies capability	SHA-256 f0d1f38f (the full hash is in the reference list); manuscripts and message headers: DOI 10.17605/OSF.IO/QASRK	Times signed by the mail servers: the sender's DKIM signature (02:45:30 UTC) and Google's ARC set (sealed 02:45:31 UTC with Google's own key) both cover the Date field, 02:45:18 UTC; both verified on 8 October 2026 against the keys in DNS (header block and check script: OSF QASRK)
2 January 2026 (print); 6 January 2026 (ebook)	The book *Infinite Architects*, whose Author's Note (pages 43 to 63) states the position on the polymathic method quoted in Section 4.2	ISBN 978-1806056200; first edition as printed: osf.io/dqm3e	Dates the paper records for the two editions; the deposit of the first edition as printed is dated by OSF's server (26 August 2026)
22 January 2026	Paper II first published: the author's independent formalisation of the comparison between sequential and parallel reasoning (Section 4.2)	DOI 10.17605/OSF.IO/8FJMA	Deposit dated by its server (OSF)
3 July 2026	This paper first published: the profile and the Capability-Adjustment Fallacy named, and the documented case placed on the public record	DOI 10.17605/OSF.IO/RBHDP	The first-publication date the paper records; its OSF component is dated by OSF's server 4 July 2026
12 August 2026	The incremental-validity test of Section 10, drafted as a programme follow-on study and preregistered by timestamp, awaiting human submission	Unit 64 of the programme's register; first anchored in Bitcoin block 962066, anchored again in block 965152 (2 September 2026)	Bitcoin anchors, as Section 2 states

C Notation and glossary

C.1 Notation

Table 5. Notation.

Symbol	Meaning
$U = I \times R^{\alpha}$	The ARC Equation of Law I, the ARC Principle (Section 4.2): usable capability U, base intelligence I, recursive depth R and the capability-growth exponent α, as the Operational Definitions register defines them
r_{g}	Genetic correlation (Section 4.3)
p	The p-value reported with that correlation
P12, P15, P21	Propositions of the theory registration: P15 carries Law IV, and P12 and P21 carry Law V (Section 8.1)

C.2 Glossary

Table 6. Glossary of the paper's terms, each with the place it is defined or used.

Term	Meaning
Polymathic Neurodivergent Profile (PNP)	A descriptive construct, stated as a hypothesis, of six interacting components (Definition 1, Table 1)
Capability-Adjustment Fallacy	The inference that because a person can perform a high-level task, they cannot require adjustments for lower-level procedural demands (Definition 2)
Twice-exceptional (2e)	Simultaneously gifted and neurodivergent, with peaks in the gifted range and valleys in the impaired range; a profile, not a diagnosis (Section 3.3)
Asynchronous development	An internal mismatch among cognitive, emotional and procedural domains (Section 3.3)
Monotropism	The tendency for attention to be pulled strongly into a narrow attention tunnel, with transitions experienced as costly (Section 3.2)
Hyperfocus	Complete absorption in a task to the point where a person appears to tune out everything else (Section 3.2)
Executive asymmetry	Disproportionate impairment in routine administration, timekeeping, correspondence, filing, scheduling, task-switching and procedural housekeeping (component 5, Table 1)
Masking, or camouflaging	Learned strategies that conceal autistic difficulties, so that high apparent functioning can conceal, rather than refute, support needs (Sections 5 and 6.2)
Autistic burnout	Chronic exhaustion, skill loss and reduced tolerance, distinct from ordinary occupational burnout (Section 6.2)
Reasonable adjustments	The duty in section 20 of the Equality Act 2010 where a provision, criterion or practice places a disabled person at a substantial disadvantage (Section 12)
Public Sector Equality Duty	The duty in section 149 of the Equality Act 2010 to have due regard to advancing equality of opportunity (Section 12)
CPR PD1A	Practice Direction 1A of the Civil Procedure Rules, on the participation of vulnerable parties or witnesses (Section 12)

Term	Meaning
NICE CG142	The clinical guideline of the National Institute for Health and Care Excellence on autism spectrum disorder in adults (Sections 3.1 and 5)
Sequential scaling and parallel self-consistency	Reasoning chains that build on their previous attempts, set against independent chains run side by side whose answers are voted (Section 4.2)
DKIM and ARC (Section 7.3)	DomainKeys Identified Mail, a signature made for the sending domain's mail server, and the Authenticated Received Chain, a seal added by a later server, here Google's; this ARC is not the ARC Theory
The ARC Theory	The Theory of Artificial Recursive Creation, the founding theory of Recursive Dynamics, the field the author founded; it is stated with five laws, each a law under test, and this paper sits outside it (Sections 2 and 8.1)
The HRIH monograph	A speculative hypothesis on where recursive self-improvement ends, stated with its predictions and kept apart from the programme's tested claims (Section 7.3)
