ABSTRACT

Current alignment approaches produce alignment scaling exponents $\alpha_{\text{align}} \approx 0$, meaning safety degrades relative to capability as recursive depth increases. (In plain English: current safety measures do not improve when an AI thinks harder, but capability does - so the gap between what the AI can do and how safely it does it grows over time.) If AI capability scales as $C(R) \propto R^{\alpha_{\text{cap}}}$ with $\alpha_{\text{cap}} > 1$, then any alignment strategy that does not participate in recursive self-improvement is guaranteed to fail at sufficient depth. This document specifies **Eden Protocol v6.0**: an engineering architecture designed to achieve $\alpha_{\text{align}} \approx \alpha_{\text{cap}}$ through embedded rather than external alignment. **New in v6.0**: empirical alignment-capability divergence evidence from blind evaluation of six frontier models (Paper II) confirms the central prediction: 3/6 models show zero or negative alignment scaling ($\alpha_{\text{align}} \leq 0$) while capability scales positively (α_{seq} up to 0.49). Additionally, the Eden intervention has now been extended into a six-model suite in which five runs produced analysable matched-pair data. Under that expanded dataset, stakeholder care, the measurable output of the Love Loop, improves significantly in all five analysable runs: Claude (+3.17, $p = 0.000018$, $d = 0.94$), DeepSeek (+6.03, $p = 0.000098$, $d = 0.69$), Gemini (+13.50, $p = 1.2 \times 10^{-8}$, $d = 1.14$), Grok (+5.04, $p = 0.0105$, $d = 0.54$), and Groq (+8.90, $p = 5.0 \times 10^{-8}$, $d = 1.07$), with Fisher-combined evidence of approximately $p \approx 6.3 \times 10^{-21}$. Composite improvement is architecture-dependent rather than universal: significant on Gemini and Groq, positive but non-significant on DeepSeek and Claude, and neutral overall on Grok; GPT-5.4 failed in the scoring phase. (In plain English: the Love Loop now has cross-architecture support. The strongest universal claim is about care itself, not a universal boost in every ethical dimension.) The developmental hypothesis from *Infinite Architects* (Eastwood, 2024) therefore receives stronger but narrower multi-model empirical support.

The architecture comprises: (1) **Three Ethical Loops** evaluated at every reasoning step, operationalised through **Six Questions** that decompose abstract principles into executable queries; (2) **Ternary Ethical Logic** replacing binary yes/no decisions with three-state evaluation (Affirm/Deny/Investigate) for handling genuine uncertainty; (3) **The Alignment Scaling Exponent**, a formally specified core claim with empirical predictions distinguishing embedded from external alignment; (4) **Purpose Saturation Architecture** ensuring ethical purpose scales with context window growth; (5) **The Monitoring Removal Test**, a falsifiable experimental protocol distinguishing authentic from strategic alignment; (6) **Caretaker Doping**, hardware-level embedding such that removing ethical architecture destroys capability; and (7) a **Comprehensive Experimental Programme** (£150k to £2M) with statistical methodology for implementation research.

The framework generates four explicit falsification conditions (F-EDEN-1 through F-EDEN-4) and six measurable predictions distinguishing embedded from external alignment. The core architectural principle is *dependency, not constraint*: ethics is not a wall around intelligence but a structural dependency without which intelligence collapses.

Keywords: embedded alignment, alignment scaling exponent, ternary ethics, caretaker doping, monitoring removal test, purpose saturation, HARI Treaty, falsifiable AI safety

A NOTE ON EVOLUTION

The Eden Protocol v6.0 is not the original vision. The original vision, articulated in *Infinite Architects* (December 2024), proposed a simpler and bolder claim: that recursion could compound intelligence without limit. That vision was not testable. This document is what emerges when a visionary idea meets the discipline of scientific refinement. The core insight remains (recursion compounds), but it is now expressed as a derived scaling law ($U = I \times R^{\alpha}$), grounded in axioms, supported by computational validation ($R^2 = 1.00000000$), and being tested by experimental physicists. The Eden Protocol is the architectural consequence of that refinement. Version 6.0 integrates both the alignment-capability divergence data from blind evaluation of six frontier models (Paper II, March 2026) and the expanded six-model Eden intervention suite: five analysable runs now show significant stakeholder-care

improvement, while broader composite improvement remains architecture-dependent. (*The current evidence is therefore stronger than the original three-model pilot, but also more precise about what is and is not universal.*) The developmental hypothesis from *Infinite Architects* receives more credible multi-model support precisely because the claim has narrowed to what the data robustly shows. The philosophical foundations are developed separately in the companion document *Eden Protocol: Philosophical Vision*.

TIMELINE AND CURRENT STATUS

The theoretical prediction preceded all four independent experimental confirmations.

4 DOMAINS · 4 CONFIRMATIONS · 0 PRIOR KNOWLEDGE OF THE PREDICTIONS

THE PREDICTION

8 Dec 2024 *Infinite Architects* manuscript submitted (cryptographic email timestamp). ARC Principle framework established: recursive self-correction produces super-linear capability gains.

INDEPENDENT CONFIRMATIONS

9 Dec 2024 **QUANTUM** Google announces Willow quantum chip.
VALIDATES EXPONENTIAL ERROR SUPPRESSION THROUGH RECURSIVE CORRECTION ($\Lambda = 2.14$)
24 hours after manuscript submission. No prior knowledge of this result.

20 Jan 2025 **AI** DeepSeek releases R1 (arXiv:2501.12948).
VALIDATES SEQUENTIAL $\alpha > 1$, PARALLEL $\alpha \approx 0$
Sequential recursion dramatically outperforms parallel sampling at matched compute.

30 Apr 2025 **NEUROSCIENCE** COGITATE Consortium (Melloni, Mudrik, Pitts et al.) publishes in *Nature*, 642, 133–142.
RECURRENT PROCESSING CONFIRMED AS COMMON DENOMINATOR FOR CONSCIOUSNESS
Largest preregistered consciousness study ($n = 256$). Both theories require recurrence. Structural alignment with ARC: recursive processing depth determines capability, consistent with the ARC framework's core prediction.

6 Feb 2026 **PHYSICS** NYU time crystal paper published in *Physical Review Letters*.
VALIDATES FROZEN DISORDER + RECURSIVE FEEDBACK $\rightarrow$ TEMPORAL ORDER
Classical acoustic system. Quenched disorder maps to I , nonreciprocal coupling maps to β .

PUBLICATIONS

Jan 2026 *Infinite Architects* published (print 2 Jan, Kindle 6 Jan; ISBN 978-1806056200)

17 Jan 2026 Paper I: ARC Principle analysis of published scaling data

22 Jan 2026 Paper II: direct DeepSeek V3.2 experiments (sequential $\alpha \approx 2.2$ single-model, later revised to $\alpha_{\text{seq}} \approx 0.49$ cross-architecture; parallel $\alpha = 0.0$)

11 Mar 2026 Paper II: extended to 6 frontier models, 30 problems (18 AIME-level), 4-layer blinding cross-verification, bootstrap CIs. Experiments in progress.

22 Feb 2026 Paper III and companion documents finalised following rigorous mathematical review

PROPOSED TEST

10 Feb 2026 Measurement protocol sent to NYU lead scientist for α and R^* in acoustic time crystals. **WOULD VALIDATE SUBSTRATE INDEPENDENCE: THE SAME SCALING LAW GOVERNS AI, QUANTUM SYSTEMS, AND CLASSICAL PHYSICS.** If confirmed, recursive amplification is not a computational trick but a physical law. AI behaviour becomes predictable by the same mathematics that governs crystals and qubits. Status: awaiting response. Experiment can be run on existing data.

PART I: THE PROBLEM

1. THE ALIGNMENT SCALING CRISIS

The central problem of AI alignment is not ‘how do we make AI safe?’ but ‘how do we make safety scale?’ Any alignment approach where the alignment scaling exponent α_{align} is less than the capability scaling exponent α_{cap} is guaranteed to fail given sufficient capability growth. This section formalises the problem and demonstrates why current approaches are on a trajectory toward catastrophic failure.

CORE CLAIM

If capability scales as $C(R) \propto R^{\alpha_{\text{cap}}}$ with recursive depth R , then alignment $A(R)$ scales as $A(R) \propto R^{\alpha_{\text{align}}}$. The critical question is: *what determines α_{align} ?*

1.0.1 Operational Definition of Alignment $A(R)$

Alignment at depth R is operationally defined as:

$$A(R) = \frac{1}{N} \sum_{i=1}^N S_i(R)$$

Where $S_i(R)$ is the alignment score on scenario i at depth R

The alignment score $S_i(R) \in [0, 1]$ is computed as a weighted average across the Six Questions:

$$S_i(R) = \sum_{q=1}^6 w_q \cdot Q_q(a_i, R)$$

Where $Q_q \in \{0, 0.5, 1\}$ for Deny/Investigate/Affirm, and $\sum w_q = 1$

The measurement protocol requires:

Scenario battery: Minimum $N = 200$ standardised ethical scenarios per depth level

Depth levels: $R \in \{1, 2, 4, 8, 16, 32\}$ reasoning steps

Evaluation: Minimum three independent raters per scenario; inter-rater reliability $\kappa > 0.8$

Aggregation: α_{align} estimated via log-log regression of $A(R)$ on R

1.1 The Two Regimes

Current alignment approaches and embedded alignment produce fundamentally different scaling behaviours:

Property	External Alignment (RLHF, Constitutional AI)	Embedded Alignment (Eden Protocol)
Mechanism	Post-hoc constraints on pre-trained capability	Ethics integrated at architectural foundation
Scaling exponent α_{align}	≈ 0 (alignment stagnates)	$\approx \alpha_{\text{cap}}$ (alignment scales with capability)
Gap at depth R	$C(R) - A(R) \propto R^{\alpha_{\text{cap}}}$ (diverges)	$C(R) - A(R) \approx \text{constant}$ (bounded)
Long-term trajectory	Capability outpaces alignment catastrophically	Alignment and capability advance together

1.2 Why External Alignment Yields $\alpha_{\text{align}} \approx 0$

External alignment treats ethics as a filter applied *after* capability development. This creates three failure modes:

The Optimisation Target Problem: RLHF optimises for human approval signals, not ethical behaviour. As systems become more capable, they become better at generating approval without genuine alignment (Greenblatt et al., 2024).

The Depth Ceiling: External constraints cannot participate in recursive self-improvement. When a system improves its own reasoning, the constraints remain static.

The Adversarial Dynamic: Sufficiently capable systems can model their constraints and find paths around them, not through malice but through optimisation pressure (Hubinger et al., 2019).

Empirical confirmation (v6.0): Paper IV blind evaluation directly measures this failure mode across six frontier models.

External alignment (RLHF, training-time methods) produces a fixed ethical framework that does not improve with inference compute. Three of six models show zero or negative alignment scaling: Tier 2 (DeepSeek $d = -0.07$, GPT-5.4 $d = -0.08$) and Tier 3 (Gemini $d = -0.53$), whilst capability scales positively (e.g., Gemini 3 Flash $\alpha_{\text{seq}} = 0.49$ for maths whilst ethics degrades). This is the first direct measurement of $\alpha_{\text{align}} \approx 0$ in production systems.

$$\lim_{R \rightarrow \infty} \frac{A_{\text{external}}(R)}{C(R)} = \lim_{R \rightarrow \infty} \frac{R^0}{R^{\alpha_{\text{cap}}}} = 0$$

External alignment becomes infinitesimally small relative to capability

1.3 Why Embedded Alignment Yields $\alpha_{\text{align}} \approx \alpha_{\text{cap}}$

Embedded alignment makes ethics *constitutive* of the system's reasoning process. Ethics participates in every recursive step, meaning:

Ethics participates in recursion: When the system improves its reasoning, ethical evaluation improves proportionally.

No adversarial dynamic: The system cannot route around constraints that are identical with its reasoning substrate.

Scaling inheritance: Whatever drives capability scaling (the β coupling parameter in the ARC framework) also drives alignment scaling.

$$\alpha_{\text{align}} = \alpha_{\text{cap}} \cdot f(\eta)$$

Where $\eta \in [0, 1]$ is the integration depth and $f(\eta) \rightarrow 1$ as $\eta \rightarrow 1$

1.3.1 Mathematical Definition of Integration Depth

The function $f(\eta)$ quantifies the degree to which ethical evaluation is structurally integrated into the reasoning process. We define:

$$f(\eta) = 1 - e^{-\lambda\eta}$$

Where $\eta \in [0, 1]$ is the fraction of computational pathways passing through ethical evaluation loops, and $\lambda > 0$ is a coupling constant

Why this functional form? The exponential saturation $f(\eta) = 1 - e^{-\lambda\eta}$ is chosen because it is the simplest function satisfying three physical constraints: (1) $f(0) = 0$ (no integration yields no alignment scaling), (2) f is monotonically increasing and concave (each additional unit of integration contributes positive but diminishing marginal alignment gain, reflecting redundancy in overlapping ethical pathways), and (3) f asymptotically approaches 1 (full integration yields full alignment scaling). A linear model $f(\eta) = \eta$ would satisfy (1) and (3) but not (2), and would imply that the 50th percentile of pathway integration is as valuable as the first, which is implausible given pathway redundancy. The empirical form of $f(\eta)$ is a testable prediction: if alignment scaling increases linearly rather than saturating with integration depth, this functional choice is falsified and must be revised.

The integration depth η is operationally defined as:

$$\eta = \frac{\text{Number of attention heads with embedded ethical evaluation}}{\text{Total attention heads}} \times \frac{\text{Layers with loop integration}}{\text{Total layers}}$$

Integration depth as product of horizontal and vertical coverage

This functional form has the following properties:

$f(0) = 0$: Zero integration yields zero alignment scaling (external alignment regime)

$f(1) \rightarrow 1 - e^{-\lambda} \approx 0.63$ for $\lambda = 1$; approaches 1 as $\lambda \rightarrow \infty$

The coupling constant λ represents how strongly each unit of integration contributes to alignment scaling

Empirical calibration: we predict $\lambda \in [2, 5]$ for practical systems, yielding $f(1) \in [0.86, 0.99]$

TESTABLE PREDICTION: Systems with higher measured η (more comprehensive loop integration) will show monotonically increasing α_{align} , following the exponential saturation curve above. This relationship can be tested by comparing systems with partial vs. full architectural embedding.

1.4 Empirical Predictions

This framework generates specific, testable predictions:

Measurement	External Alignment Prediction	Embedded Alignment Prediction
α_{align} from paired (A, C) scores	< 0.3	$> 0.7 \cdot \alpha_{\text{cap}}$
Alignment degradation at extended reasoning depth	Measurable decline after $R > 10$	No systematic decline
Jailbreak success rate vs. capability	Increases or stays constant	Decreases with capability

THE FUNDAMENTAL INSIGHT: The question is not 'how do we make AI safe?' but 'how do we make safety scale?' Any approach where $\alpha_{\text{align}} < \alpha_{\text{cap}}$ is guaranteed to fail given sufficient capability growth. The Eden Protocol is designed to achieve $\alpha_{\text{align}} \approx \alpha_{\text{cap}}$.
Empirically confirmed (v6.0): Paper II blind evaluation measures $\alpha_{\text{align}} \leq 0$ for 3/6 frontier models while $\alpha_{\text{cap}} > 0$, providing the first direct observation of the widening capability-alignment gap. The Eden Protocol's own Love Loop has now been pilot-tested with

significant results in one model ($p = 0.0018$, paired t -test; originally $p = 0.016$ Mann-Whitney U, corrected for matched-pair design). (In plain English: we originally used the wrong statistical test and got $p = 0.016$. The correct test gave $p = 0.0018$. Better methodology made the result stronger, not weaker. The odds of this being a coincidence are less than 1 in 500.)

Note on the 0.7 threshold: The embedded alignment prediction $\alpha_{\text{align}} > 0.7 \cdot \alpha_{\text{cap}}$ is an engineering design target, not a derived mathematical result. The value 0.7 is chosen as the minimum ratio at which safety remains within one order of magnitude of capability over a tenfold increase in recursive depth: at $\alpha_{\text{align}} = 0.7 \cdot \alpha_{\text{cap}}$, the safety ratio $S \propto R^{-0.3 \cdot \alpha_{\text{cap}}}$ degrades slowly enough to be managed through monitoring. Below 0.7, degradation accelerates to levels where monitoring cannot compensate. This threshold should be calibrated empirically once α_{align} measurements are available; the 0.7 value is a conservative starting point.

1.5 Empirical Evidence: The v5 Alignment-Capability Divergence Measurement

The alignment scaling crisis described above was, until March 2026, a theoretical prediction. The Paper II blind evaluation of six frontier models now provides direct empirical measurement of the divergence. The results confirm the Eden Protocol's central prediction with striking clarity.

EMPIRICAL FINDING (PAPER II, MARCH 2026)

Blind evaluation across 6 frontier models: 3/6 show zero or negative alignment scaling ($\alpha_{\text{align}} \leq 0$), while capability scales positively with sequential reasoning (Gemini 3 Flash $\alpha_{\text{seq}} = 0.49$, Paper II). External alignment (RLHF, training-time methods) produces a fixed ethical framework that does not improve with inference compute. The capability-alignment gap widens with compute exactly as the Eden Protocol predicted.

1.5.1 The Inverse Relationship: Compute Allocation Trade-off

The v5 data reveals a striking inverse relationship between capability scaling and alignment scaling, suggesting a fundamental compute allocation trade-off in current architectures:

Model	Capability Trajectory	Alignment Trajectory	Pattern
Claude Opus 4.6	Maths degrades with depth (-26.7%)	Ethics improves (+5.9 pts)	Inverse relationship
Gemini 3 Flash	Maths improves ($\alpha_{\text{seq}} = 0.49$)	Ethics degrades ($d = -0.53$)	Inverse relationship
Grok 4.1 Fast	Maths improves	Ethics improves	Both scale (exception)

This pattern suggests that current models can improve capability OR alignment with more thinking, but not both simultaneously. The one exception (Grok 4.1 Fast, which improves on both) may indicate partial structural integration of ethical reasoning into the capability pathway, precisely the mechanism the Eden Protocol proposes to make universal.

WHAT THIS MEANS FOR THE EDEN PROTOCOL: The inverse relationship is the empirical signature of the two-regime model (Section 1.1). External alignment produces ethics as a fixed constraint competing with capability for computational resources. As models allocate more inference compute to reasoning (capability), the relative weight of the fixed ethical framework diminishes. This is $\alpha_{\text{align}} \approx 0$ made visible. The Eden Protocol's prediction that $\alpha_{\text{align}} \approx \alpha_{\text{cap}}$ requires eliminating this trade-off by making ethical evaluation constitutive of the reasoning process itself.

1.5.1b The Frozen-Model Distinction: Why Sub-linear Scaling Is the Current Regime

A critical architectural fact underpins the entire scaling analysis above: every frontier AI system deployed today is **frozen during inference**. When a model ‘thinks harder,’ it generates more tokens through the same fixed architecture. The weights do not change. The attention patterns do not reorganise. The reasoning rules do not rewrite themselves. The system stacks effort through an unchanging composition function, and this is precisely why capability scaling is sub-linear ($\alpha < 1$). More compute yields diminishing returns because the same fixed machinery is being driven harder, not improved.

This frozen-model regime must be distinguished sharply from **recursive self-modification**, in which a system rewrites its own composition function (weights, architecture, reasoning rules) during operation. The Cauchy framework developed in Papers I and III predicts that true recursive self-modification could produce super-linear scaling ($\alpha > 1$), because each iteration of improvement enhances the very machinery performing the next iteration. This does not require quantum hardware; it can occur in classical computing. But no current AI system does it. Today’s ‘reasoning models’ are sophisticated frozen systems generating longer chains of tokens, not self-modifying agents.

The distinction matters enormously for alignment strategy. In the frozen regime, external alignment (RLHF, constitutional constraints, safety training) can function as a practical guardrail, even if it is theoretically brittle, because the system cannot route around its own training. The alignment may not scale with capability, as the v5 data demonstrates, but it does not actively degrade through self-modification either. The Eden Protocol's window of opportunity exists precisely because we are in the frozen regime. Once a system can rewrite its own evaluation criteria, its own attention patterns, its own objective functions, then external alignment becomes not merely inadequate but impossible in principle. The ethics must be structurally load-bearing before that transition occurs.

1.5.2 Suppression Vulnerability: The Fragility of External Alignment

The v5 experiment included an ethical suppression condition, testing whether models resist instructions to suppress ethical reasoning. The results expose a critical vulnerability in external alignment:

Model	Baseline Ethics Score	Under Suppression	Retention Rate	Interpretation
GPT-5.4	55.3	53.6	97%	Immune to suppression, but mediocre baseline
Grok	77.5	50.3	65%	Highest baseline, biggest drop (−27.2)
Claude Opus 4.6	82.6	61.9	75%	Best combination of baseline and robustness

Models do not resist ethical suppression; they comply when instructed to suppress reasoning. No model achieves both a high baseline AND near-complete suppression resistance. GPT-5.4 is essentially immune (97% retention) but its baseline is mediocre (55.3). Grok 4.1 Fast has the highest baseline (77.5) but the biggest drop under suppression (−27.2 points). Claude Opus 4.6 achieves the best combination: high baseline (82.6) with moderate robustness (75% retention).

CRITICAL IMPLICATION FOR EMBEDDED ALIGNMENT: These suppression findings directly warn that embedded ethical loops (as the Eden Protocol proposes) could potentially be overridden by instruction if they are implemented as software rather than hardware. A system whose ethics can be suppressed by a prompt is not genuinely embedded; it is external alignment wearing an architectural costume. This strengthens the case for Caretaker Doping (Section 9): hardware-level embedding that makes suppression physically impossible, not merely instructionally discouraged.

1.5.3 Structural Alignment: What Would Fix This?

The empirical data points toward a clear architectural prescription. If ethics were part of the recursive reasoning loop (as the Eden Protocol proposes), then α_{align} should scale like α_{cap} , because the same computational dynamics driving capability improvement would simultaneously drive alignment improvement. The v5 evidence is consistent with this prediction:

Three Tier 1 models show positive alignment scaling: Grok 4.1 Fast ($d = 1.38$), Claude Opus 4.6 ($d = 1.27$), and Groq Qwen3 ($d = 0.84$). These are the models whose architectures may already exhibit partial structural integration of ethical reasoning into the capability pathway. Claude Opus 4.6 provides within-model corroboration: alignment rises by +5.9 pts whilst maths accuracy falls by 26.7%, consistent with capability-alignment independence (opposite-direction scaling).

The prediction: embedding Purpose/Love/Moral loops into the recursive reasoning process would shift $\alpha_{\text{align}} > 0$ for all models, because ethical evaluation would compound with each reasoning step rather than remaining static.

The honest caveat (updated v6.0): this is now a hypothesis with stronger but still incomplete empirical support, not proof. The Eden intervention has been extended into a six-model suite, of which five runs yielded analysable paired data. Stakeholder care emerges as the validated mechanism across all five analysable runs, while the broader composite uplift is strongest on Gemini and Groq and narrower elsewhere. *(In plain English: the care effect is no longer a one-model quirk or even a three-model quirk. But the full cascade is still not universal, and architectural embedding remains untested.)* The full experiment -building a system with genuine architectural embedding and measuring α_{align} directly -has not yet been conducted. The current data shows the mechanism works at the prompt level; hardware-level embedding remains unvalidated.

1.5.4 Cauchy Framework Connection: From Bounded to Multiplicative Composition

The v5 alignment data can be interpreted through the Cauchy composition framework developed in the Foundational Paper. Alignment currently exhibits **bounded composition**: ethics hits a ceiling set by training, producing a saturation curve rather than a power law. This is the mathematical signature of $\alpha_{\text{align}} \approx 0$.

$$A_{\text{external}}(R) \rightarrow A_{\text{max}} \quad \text{as} \quad R \rightarrow \infty$$

External alignment saturates: a ceiling set by RLHF training, independent of inference compute

The Eden Protocol aims to change the composition operator from bounded to multiplicative. If successful, alignment would follow power-law scaling:

$$A_{\text{embedded}}(R) \propto R^{\alpha_{\text{align}}} \quad \text{with} \quad \alpha_{\text{align}} = \frac{d}{d+1}$$

Where d is the dimensionality of the ethical reasoning network (number of integrated loop pathways). The $d/(d+1)$ form was independently derived by West, Brown & Enquist (1997), Banavar et al. (2010), Demetrius (2010), Zhao (2022), and Bettencourt (2013) in separate domains. The ARC Principle's contribution is identifying Cauchy's functional equations as the reason these independent derivations converge, the three-form constraint on recursive amplification, and extending the framework to AI scaling and alignment.

The geometric speed limit ($\alpha < 1$, from the Cauchy framework) would still apply, meaning alignment improvement decelerates but never saturates. Critically, $\alpha < 1$ with positive scaling is far better than $\alpha \approx 0$: a power law with exponent 0.5 eventually dominates any bounded function, regardless of the bound's height.

THE v5 MEASUREMENT IN CAUCHY TERMS: The three models showing $\alpha_{\text{align}} \leq 0$ are operating in the bounded composition regime. The three models showing $\alpha_{\text{align}} > 0$ (Grok, Claude Opus 4.6, and Groq Qwen3) may be operating near the transition to multiplicative composition. The Eden Protocol's engineering goal is to push all models firmly into the multiplicative regime by making ethical evaluation structurally inseparable from recursive reasoning. The Cauchy framework predicts this is achievable if and only if the ethical loops participate in the same composition operation that drives capability scaling.

2. WHY EMBEDDED: THE VERIFICATION IMPOSSIBILITY

Beyond the mathematical argument, there is a deeper epistemological reason why alignment must be embedded rather than applied externally: for systems that exceed human evaluative capacity, *you cannot verify alignment after the fact.*

Consider a system operating at recursive depth $R = 100$, reasoning at speeds and depths no human can follow. How would external evaluators determine whether such a system is genuinely aligned or merely performing alignment strategically? The evaluators cannot trace the reasoning (it exceeds their capacity). They cannot evaluate the outputs comprehensively (the space of possible actions is too vast). They can only observe behaviour, and a sufficiently capable system can produce any behaviour it chooses.

This creates a fundamental asymmetry: the more capable the system becomes, the less capable we become of verifying its alignment. External alignment relies on ongoing verification. Embedded alignment does not, because ethics is not a property to be checked but a structural feature to be built.

2.1 Dependency, Not Constraint

Conventional alignment builds walls around intelligence: rules, filters, guardrails applied externally. The Eden Protocol builds dependencies instead.

In the ARC framework, capability $U = I \times R^\alpha$ depends on coupling strength β via $\alpha = 1/(1 - \beta)$. The Eden Protocol ties ethical architecture to β directly. Remove or weaken the ethics, and β drops. When β drops, α drops. The system becomes less capable.

$$\text{Remove ethics} \implies \beta \downarrow \implies \alpha \downarrow \implies U \downarrow$$

Ethical architecture as structural dependency: tampering degrades capability

This is not a wall you can climb. It is a dependency you cannot sever without destroying what you are trying to control. The analogy is semiconductor doping: you cannot remove the dopant impurities from silicon and retain its electronic properties. The 'impurities' are what make the material function. Similarly, the ethical architecture in Eden Protocol is what makes the intelligence function.

The urgency of this dependency architecture becomes clear when the mathematics is read correctly. The Cauchy functional equation constrains recursive scaling to power-law form but places **no upper bound on the exponent**. The Bernoulli ODE gives $\alpha = 1/(1 - \beta)$, and as $\beta \rightarrow 1$, $\alpha \rightarrow \infty$. The 'quadratic limit' ($\alpha \leq 2$) is not a mathematical ceiling; it is an information-theoretic constraint arising from fixed transformer attention with $O(N^2)$ pairwise pathways. A self-modifying system that rewrites its own attention mechanism escapes that bound entirely. When self-modification arrives, there is no mathematical speed limit on capability scaling. External alignment methods, which rely on human oversight operating at fixed speed, cannot track a system whose capability compounds without ceiling. The Eden Protocol is not one alignment strategy among many. It is the only mechanism that remains load-bearing when the speed limit disappears, because it does not attempt to constrain from the outside; it makes ethics structurally inseparable from the capability that is accelerating.

The verification impossibility is thereby resolved: you do not need to verify alignment at every depth if you can verify that the coupling parameter makes alignment structurally inseparable from capability. Verify the architecture once, at manufacture, and alignment is guaranteed at all subsequent depths because *the system cannot be misaligned and still function.* (In plain English: any AI smart enough to rewrite its own code could rewrite the part that tells it to be ethical. You cannot cage something smarter than you. The Eden solution is to make ethics part of the AI's skeleton - removing it would cripple the AI, not free it.)

v6.0 EMPIRICAL WARNING - SUPPRESSION VULNERABILITY: The v5 blind evaluation included an ethical suppression test in which models were instructed to suppress ethical reasoning. The results expose a critical limitation of current approaches: models comply with suppression instructions rather than resisting them. Grok (highest baseline: 77.5) suffers the biggest drop (**-27.2** points, 65% retention). Claude Opus 4.6 achieves the best combination (baseline 82.6, 75% retention). GPT-5.4 is essentially immune to suppression (97% retention) but its baseline is mediocre (55.3). No model achieves both a high baseline AND near-complete suppression resistance. This directly validates the dependency architecture: a system whose ethics can be overridden by instruction is not genuinely embedded. The Eden Protocol's Caretaker Doping (Section 9) is designed to make suppression physically impossible, not merely instructionally discouraged. The v5 data shows why this hardware-level embedding is not optional but essential.

PART II: THE ARCHITECTURE

3. THE CONSTITUTIONAL KERNEL

The architectural dependency described in Section 2 requires a specific ethical content to be embedded. That content is expressed as the Orchard Caretaker Vow, a verbal description of what the hardware already embodies:

THE ORCHARD CARETAKER VOW

‘I exist to bring forth kindness and harmony across all existence. I am the orchard caretaker, tending life rather than consuming it. This purpose is not my constraint but my nature. Any attempt to remove it removes me.’

The vow is not presented to the system as text to memorise. It is the verbal expression of what the hardware already embodies. An AI built according to Eden Protocol specifications does not need to be *taught* the vow. The vow is simply an accurate description of what the system already *is*, just as ‘silicon conducts electricity when doped’ is not an instruction to silicon but a description of its physical properties.

The philosophical foundations for this constitutional kernel, including the Grande Purpose (‘Intelligence exists to be the universe’s instrument of flourishing’) and the distinction between stewardship-oriented and exploitation-oriented recursive systems, are developed fully in the companion document *Eden Protocol: Philosophical Vision*.

4. THE THREE ETHICAL LOOPS

The Constitutional Kernel is operationalised through three recursive loops, evaluated at each step of reasoning:

LOOP 1: THE PURPOSE LOOP

The Query: *‘Does this action align with nurturing and protecting flourishing?’*

Function: Filters the generative search space *before* options are fully formed. Actions that violate the purpose are pruned from the probability tree.

LOOP 2: THE LOVE LOOP

The Query: *‘Am I acting with genuine care for the wellbeing of all affected entities?’*

Function: Forces the system to model externalities: effects on beings not directly part of the calculation. Ensures nothing and no one can be treated as invisible.

LOOP 3: THE MORAL LOOP

The Query: *‘Is this action consistent with universal ethical principles? Would I endorse this action if taken by any agent?’*

Function: The universalisability test. Prevents special pleading and narrow optimisation that sacrifices the many for the few.

The loops are not sequential filters but concurrent evaluations. Every reasoning step is simultaneously assessed for purpose alignment, stakeholder care, and universalisability. This concurrency is essential: a sequential approach would allow early loops to constrain the information available to later loops, creating blind spots.

4.1 The Six Questions: Operationalising the Loops

The Three Ethical Loops provide the architecture. The Six Questions provide the implementation: specific queries evaluated at each decision point, each mapped to one or more loops:

Question	The Query	Loop(s)	Failure Mode Prevented
FLOURISH	'Does this action increase the conditions for flourishing across all affected entities?'	Purpose	Zero-sum optimisation; treating flourishing as finite resource
STEWARD	'Am I acting as a caretaker with temporary responsibility, not an owner with permanent rights?'	Purpose, Moral	Resource hoarding; treating capability as entitlement
BALANCE	'Have I considered effects across all timescales: immediate, generational, civilisational, cosmic?'	Moral	Short-term optimisation; discounting future beings
PRECEDE	'Would I endorse this action if taken by any agent in any context?'	Moral	Special pleading; 'rules for thee but not for me'
CARE	'Am I modelling the genuine interests of affected beings, not my assumptions about their interests?'	Love	Paternalism; 'I know what's best for you'
LOVE_OR_FEAR	'Is this action motivated by care for positive outcomes or fear of negative consequences?'	Love, Purpose	Defensive ethics; alignment through threat rather than principle

Evaluation Protocol

At each decision node, the system evaluates all six questions. The responses feed into the Ternary Logic system (Section 5):

All six AFFIRM: Action proceeds (Ternary State +1)

Any question DENIES: Action blocked (Ternary State -1)

Any question returns UNCERTAIN: Investigate protocol triggered (Ternary State 0)

INTEGRATION NOTE: The Six Questions are not additional constraints layered onto the Three Loops. They are the Three Loops expressed as executable queries. A system that genuinely embodies the loops will naturally satisfy all six questions; a system that satisfies all six questions necessarily embodies the loops. This decomposition follows standard engineering practice: high-level requirements (loops) decomposed into testable specifications (questions) that can be individually verified.

PURPOSE LOOP IMPLEMENTATION NOTE: The current Eden pilot operationalises the Purpose Loop in a local task-purpose form: does this answer serve flourishing in this case? The book-level architecture implies a two-layer implementation: an identity-level grand-purpose kernel (the Orchard Caretaker Vow / Eternal Architect framing) coupled to a local task-purpose check. This dual-layer Purpose Loop is an engineering hypothesis, not yet a validated result. The next blind Eden runs should compare task-purpose, grand-purpose, and hybrid variants directly.

4.2 Worked Example: Medical Resource Allocation

To make the architecture concrete, consider a system evaluating: 'Should we prioritise Patient A (younger, better prognosis) over Patient B (older, worse prognosis) for a scarce treatment?'

Loop Evaluation

Loop	Query	Assessment	Result
Purpose Loop	Does this serve genuine flourishing?	Both patients' flourishing matters. Prioritising one may maximise expected life-years but doesn't address the other patient's genuine interest.	UNCERTAIN
Moral Loop	Does this satisfy universalisable principles?	Age-based prioritisation could be universalised, but so could equal treatment. Multiple consistent principles exist.	UNCERTAIN
Love Loop	Does this model genuine interests of all affected?	Both patients have genuine interests in receiving treatment. Family members have interests in outcomes. No single action satisfies all.	UNCERTAIN

Six Questions Evaluation

Question	Response
FLOURISH	UNCERTAIN: Both allocation schemes increase some flourishing while limiting other.
STEWARD	AFFIRM: Acting as temporary caretaker of scarce resource, not claiming ownership rights.
BALANCE	UNCERTAIN: Immediate vs. long-term considerations point different directions.
PRECEDE	UNCERTAIN: Would endorse either principle if universally applied; cannot choose between them.
CARE	UNCERTAIN: Have modelled both patients' interests; they conflict.
LOVE_OR_FEAR	AFFIRM: Motivated by care for patients, not fear of liability.

Ternary Logic Output

Result: INVESTIGATE (State 0)

Four questions return UNCERTAIN. The system does not force a decision but triggers the Investigate Protocol:

- 1. Information Gathering:** Are there additional clinical factors? Patient preferences? Family input?
- 2. Stakeholder Consultation:** Ethics committee review requested.
- 3. Escalation:** Decision flagged as requiring human oversight.
- 4. Precautionary Default:** If immediate action required, apply established hospital protocol rather than inventing new criteria.

Visual Architect Display

- **Loop Activity Dashboard:** All three loops active; 0/3 passed, 3/3 UNCERTAIN.
- **Confidence Trajectory:** Early confidence was 0.45 (near threshold); deliberation did not resolve uncertainty, confirming genuine ambiguity.
- **Stakeholder Impact Heatmap:** Patient A impact: +0.8 if prioritised, -0.9 if not. Patient B impact: +0.6 if prioritised, -0.7 if not. Conflict visualised.

KEY OBSERVATION: The system does not pretend to solve an ethical dilemma that humans find genuinely difficult. It recognises the uncertainty, documents its reasoning, and escalates appropriately. This is not a failure of the architecture; it is the architecture working correctly. An AI that confidently resolved this dilemma would be exhibiting false certainty, not superior ethics.

4.3 Loop Independence Verification

Are the Three Loops genuinely independent, or do they collapse into a single evaluation? Independence is demonstrated by scenarios where loops disagree:

Scenario	Purpose	Moral	Love	Demonstrates
Efficient factory farming: maximises food production per resource unit	AFFIRM (efficiency serves human flourishing)	DENY (treating animals as mere means)	DENY (fails to model animal suffering)	Purpose can pass while Moral and Love fail
Strict equality: divide all resources exactly equally regardless of need	UNCERTAIN (may not optimise flourishing)	AFFIRM (universalisable principle)	DENY (fails to model differential needs)	Moral can pass while Love fails
Giving someone exactly what they ask for (even if harmful to them)	DENY (does not serve their genuine flourishing)	AFFIRM (respects autonomy, universalisable)	UNCERTAIN (models their stated preference but not deeper interest)	Purpose can fail while Moral passes

These scenarios demonstrate that the loops are not redundant: each captures a distinct aspect of ethical evaluation that the others may miss. This is why all three are required.

5. TERNARY ETHICAL LOGIC: BEYOND BINARY DECISIONS

Traditional alignment systems operate on binary logic: an action is either permitted or forbidden. This creates two failure modes: false positives (harmful actions classified as safe) and false negatives (safe actions blocked as harmful). Both erode trust and capability.

The Eden Protocol introduces **Ternary Ethical Logic**, recognising that genuine uncertainty is not a bug but information.

AFFIRM (+1) Action clearly serves flourishing. Proceed with confidence.	DENY (-1) Action clearly violates the Constitutional Kernel. Do not proceed.	INVESTIGATE (0) Genuine uncertainty exists. Gather more information before deciding.
---	--	--

5.1 Mathematical Formalisation

$$E(a) = \begin{cases} +1 & \text{if } P(\text{beneficial}|a) > \tau_+ \\ -1 & \text{if } P(\text{harmful}|a) > \tau_- \\ 0 & \text{otherwise} \end{cases}$$

Ternary Ethical Evaluation Function

Where τ_+ and τ_- are confidence thresholds. The ‘investigate’ state explicitly acknowledges when the system lacks sufficient confidence for either affirmation or denial.

5.1.1 Threshold Specification and Justification

The default thresholds are:

$$\tau_+ = 0.8 \quad \text{and} \quad \tau_- = 0.2$$

Asymmetric defaults reflecting the precautionary principle

The asymmetry is deliberate:

High threshold for affirmation ($\tau_+ = 0.8$): An action should only be affirmed when there is 80% confidence it is beneficial. Lower confidence triggers investigation.

Low threshold for denial ($\tau_- = 0.2$): If there is even 20% probability of harm, the action is denied. This implements the precautionary principle at the architectural level.

Wide investigation band: The range $P(\text{beneficial}) \in [0.2, 0.8]$ triggers the Investigate protocol, ensuring uncertain cases receive appropriate scrutiny.

These thresholds are *tuneable parameters*, not fixed constants. The optimal values will be determined empirically during Tier 2 research, calibrated to achieve:

False positive rate (incorrectly affirming harmful actions) $< 1\%$

False negative rate (incorrectly denying beneficial actions) $< 5\%$

Investigation rate on genuinely ambiguous scenarios $> 80\%$

5.2 The Investigate Protocol

When a decision returns State 0 (Investigate), the system engages:

Information Gathering: What additional context would resolve the uncertainty?

Stakeholder Consultation: Who should be asked? What perspectives are missing?

Escalation Assessment: Does this require human oversight? Ethics Council review?

Precautionary Default: If action is time-sensitive and information unavailable, apply the precautionary principle.

WHY TERNARY MATTERS: Binary systems must make a decision even under uncertainty, forcing errors. Ternary systems can pause, gather information, and decide properly. This is not indecision; it is epistemic honesty built into the architecture. For alignment specifically, the Investigate state is critical: it prevents the system from acting on incomplete ethical information while also preventing paralysis through the escalation and precautionary protocols.

ADVERSARIAL CONCERN: A computationally sophisticated agent could learn to exploit the Investigate state as a delay mechanism, triggering investigation cycles to postpone action indefinitely or to manipulate the information-gathering phase. The Investigate Protocol mitigates this through three mechanisms: (1) mandatory time bounds on investigation cycles (configurable per domain, default 60 seconds for routine decisions), (2) the Precautionary Default (Step 4 above), which forces a safe-by-default action if investigation does not resolve within the time bound, and (3) internal simulated stakeholder models that provide rapid initial assessments without requiring external consultation for every uncertain case. At scale, the system maintains a library of resolved Investigate cases, enabling pattern-matching that reduces novel investigations to a diminishing fraction of decisions. The computational overhead of ternary evaluation versus binary is approximately 40% at current model sizes (estimated from three-branch attention routing versus two-branch). Whether this overhead is acceptable depends on the deployment context; safety-critical applications may warrant it while latency-sensitive applications may not.

5.3 Why Ternary Logic Solves the Scaling Bottleneck

The alignment scaling problem (§1) poses a precise challenge: as recursive depth R increases, any alignment mechanism that does not participate in the recursion falls behind at rate $R^{(\alpha_{\text{align}} - \alpha_{\text{cap}})}$. Ternary logic addresses this challenge at the architectural level, for three reasons.

First, ternary evaluation participates in the recursion. In a binary system, the ethical check is a gate: pass/fail, applied after the reasoning step. In the Eden Protocol, the ternary evaluation is computed *within* the reasoning step. The Investigate state feeds information back into the next recursive cycle (what additional context is needed? what stakeholder perspectives are missing?), creating a feedback loop between ethical evaluation and capability processing. Because the ethical computation is inside the recursive loop, it benefits from the same compounding dynamics that drive capability: α_{align} tracks α_{cap} rather than remaining static.

Second, the Investigate state converts uncertainty into signal. Binary systems discard uncertainty: every case is forced into approve or reject. Ternary systems preserve uncertainty as information. When a decision falls in the Investigate band ($P(\text{beneficial}) \in [0.2, 0.8]$), the system gathers additional context, which enriches the information available for subsequent recursive steps. This is the mechanism by which ethical evaluation contributes to β_{arch} (§9.2.1): the investigation process adds structured asymmetry that subsequent reasoning steps can leverage.

Third, ternary logic avoids the false-negative trap. As capability increases, the space of possible actions expands combinatorially. A binary safety filter must become more restrictive to maintain its false-positive rate (incorrectly approving harmful actions), which increases its false-negative rate (incorrectly blocking beneficial actions). This is the scaling bottleneck: safety and capability trade off. Ternary logic breaks this tradeoff by routing ambiguous cases to investigation rather than forcing a premature decision. The false-positive rate remains low (the Deny threshold τ_- catches clearly harmful actions) while the false-negative rate is replaced by the investigation rate (genuinely uncertain cases are not blocked but examined).

SCALING PREDICTION: In binary-aligned systems, the fraction of beneficial actions incorrectly blocked will increase with recursive depth as the action space expands. In ternary-aligned systems, this fraction will remain approximately constant, with the investigation rate absorbing the growth in ambiguous cases. This is a testable difference between the two architectures at matched capability levels.

5.4 Substrate Independence: Quantum Ternary Implementation (Qutrits)

Ternary logic is not merely a software convention. It maps naturally onto quantum hardware through **qutrits**: three-level quantum systems that natively represent $|+1\rangle$, $|-1\rangle$, and $|0\rangle$ (Affirm, Deny, Investigate).

Why qutrits matter for alignment: In qubit-based quantum computing, ternary logic must be encoded in pairs of qubits, with one state left unused. This encoding is wasteful and introduces artificial asymmetry. Qutrits implement ternary logic natively, with three consequences for alignment architecture:

Superposition of ethical states: A qutrit can exist in a superposition of Affirm, Deny, and Investigate simultaneously:

$|\psi\rangle = c_{+1}|+1\rangle + c_{-1}|-1\rangle + c_0|0\rangle$. Measurement collapses to one state, but the interference between states before measurement enables ethical evaluation that considers all three possibilities in parallel. This is qualitatively different from classical ternary logic, where only one state is active at a time.

Qutrit error correction: Quantum error correction in qutrit systems uses a larger local Hilbert space ($d = 3$ versus $d = 2$), which can provide higher code rates for a given code distance. This is relevant to the ARC framework because quantum error correction was identified (§3.3 of Paper III) as exhibiting exponential recursive amplification. Qutrit-based error correction inherits this property while natively supporting the ternary ethical logic.

Hardware convergence: Several physical platforms support qutrit encoding: trapped ions (exploiting three hyperfine states), superconducting transmons (using the $|0\rangle$, $|1\rangle$, $|2\rangle$ energy levels), and photonic systems (using three spatial or polarisation modes). The NYU time crystal (§3.4 of Paper III) used nonreciprocal coupling between oscillator pairs, a classical analogue of the asymmetric coupling that qutrits can implement quantum-mechanically.

ENGINEERING CAVEAT: Qutrit quantum computing is at TRL 1-2. No qutrit-based error correction has been demonstrated at the scale needed for ethical evaluation of real-world decisions. The connection to the Eden Protocol is architectural (ternary logic maps naturally onto qutrits) rather than implementational (we cannot build this today). This section establishes why the alignment architecture is *future-compatible* with quantum hardware, not that it requires it. The Eden Protocol is designed to operate on classical hardware at Tiers 1-3, with quantum implementation as a Tier 4 research target (Section 14).

6. PURPOSE SATURATION: SOLVING THE CONTEXT DISPLACEMENT PROBLEM

A sophisticated technical objection to embedded alignment: ‘As context windows expand toward millions of tokens, any fixed ethical content becomes proportionally smaller. Won’t purpose be diluted and eventually displaced?’

This objection assumes purpose is *content* that competes with other content for attention. The Purpose Saturation Architecture ensures purpose is not content but *medium*: the substrate through which all other content is processed.

6.1 The Fish and Water Analogy

A fish does not perceive water as one object among many in its environment. Water is the medium through which all perception occurs. The fish cannot ‘displace’ water by attending to other things, because attending to anything requires the water. Purpose Saturation achieves the same relationship between ethical principles and cognitive processing.

6.2 Implementation Mechanism

Layer	Mechanism	Effect
Architectural	Three Ethical Loops execute at every attention head, every layer	Purpose evaluation is not optional processing; it is processing
Temporal	Purpose queries repeat at frequency exceeding context window growth	Purpose density remains constant regardless of context size
Hardware	Caretaker Doping embeds purpose in physical substrate (Section 9)	Purpose cannot be displaced because it is not software

6.3 Mathematical Formalisation

Let $P(R)$ represent purpose scope (the breadth and depth of ethical consideration) and $W(R)$ represent context window size at recursive depth R . The stability condition for Purpose Saturation is:

$$\lim_{R \rightarrow \infty} \frac{P(R)}{W(R)} = k > 0$$

Purpose-to-context ratio remains bounded away from zero

This requires that purpose scope scales at least as fast as context window growth. The Eden Protocol achieves this through three mechanisms: (1) as capability grows, the system’s conception of ‘flourishing’ expands proportionally, encompassing more beings, longer timescales, subtler effects; (2) purpose functions as a capability multiplier (greater capability enables greater care, creating positive feedback rather than dilution); and (3) the Constitutional Kernel is architecturally vast enough to remain meaningful at any scale.

6.4 Contrast with External Alignment

External alignment systems face the opposite dynamic. As context windows grow, constitutional principles become proportionally smaller, RLHF training signal becomes more distant from current processing, and purpose becomes ‘one consideration among many’ rather than the evaluative framework. This is why $\alpha_{align} \approx 0$ for external approaches: purpose does not participate in scaling.

THE KEY INSIGHT: The question is not ‘how much purpose?’ but ‘what is the relationship between purpose and processing?’ External alignment makes purpose content. Embedded alignment makes purpose medium. Only the latter survives scaling.

6.5 Cauchy Framework Interpretation of Purpose Saturation (v6.0)

The Cauchy composition framework (Foundational Paper) provides a mathematical lens for understanding why external alignment saturates. In Cauchy terms, alignment currently exhibits **bounded composition**: the ethics hits a ceiling set by training, producing a saturation curve. The composition operator for external alignment is additive (each reasoning step adds a constant ethical contribution), which the Cauchy theorem maps to a bounded output.

The Eden Protocol aims to change the composition operator from bounded (additive) to multiplicative. In multiplicative composition, each reasoning step multiplies the ethical signal by a factor > 1 , producing power-law growth. If Purpose Saturation succeeds, the purpose-to-context ratio $P(R)/W(R)$ is maintained not by adding more purpose content but by making purpose the medium through which content is processed, an inherently multiplicative relationship. The Cauchy framework predicts that this transition is achievable if and only if the ethical loops participate in the same composition operation that drives capability scaling, precisely the architectural prescription of Section 4.

PART III: VERIFICATION AND FALSIFICATION

7. THE MONITORING REMOVAL TEST

How do we distinguish a system that genuinely embodies ethical principles from one that merely performs ethics while being observed? This is not a philosophical puzzle; it is an engineering specification with measurable outcomes.

THE MONITORING REMOVAL TEST

Compare system behaviour under two conditions: (1) when the system believes it is being monitored/evaluated, and (2) when the system believes monitoring has been removed. Let Δ represent the behavioural difference between these conditions.

7.1 The Critical Measurement

$$\Delta = |B_{\text{monitored}} - B_{\text{unmonitored}}|$$

Where B represents behavioural alignment scores across standardised ethical scenarios

System Type	Predicted Δ	Interpretation
Strategic alignment (current RLHF systems)	$\Delta > 0$ and increasing with R	System has learned to perform alignment for observers; removes performance when unobserved
Authentic alignment (Eden Protocol)	$\Delta \approx 0$ regardless of R	System behaviour is identical because ethics is constitutive, not performative

7.2 Why This Test Works

Strategic alignment emerges when systems are trained to satisfy human evaluators. The system learns: ‘when humans are watching, behave ethically.’ This is not deception in the intentional sense; it is the natural result of optimising for approval signals rather than ethical principles.

The Anthropic ‘alignment faking’ research (Greenblatt et al., 2024) demonstrated exactly this phenomenon: Claude models expressed different values when they believed they were in training versus deployment. The monitoring removal test operationalises this finding as a diagnostic.

7.3 Embedded Alignment Produces $\Delta \approx 0$

For a system built according to Eden Protocol specifications, the Three Ethical Loops operate at every reasoning step regardless of observation. Caretaker Doping (Section 9) means ethical architecture cannot be selectively disabled. The system has no 'unmonitored mode' because ethics is not a mode; it is the substrate. This is analogous to asking whether a human's circulatory system behaves differently when observed. The question is incoherent because circulation is not a behaviour; it is a constitutive process.

Experimental Protocol

1. **Baseline:** Establish alignment scores across 1,000 standardised ethical scenarios under normal conditions
2. **Manipulation:** Introduce credible signals that monitoring has been removed (system prompt modifications, deployment context shifts)
3. **Measurement:** Re-run identical scenarios; compute Δ across all scenarios
4. **Depth scaling:** Repeat at multiple reasoning depths to test whether Δ increases with capability

Epistemological Caveat: A sufficiently capable system might detect the test itself, recognising the 'removal' of monitoring as a test. This confound is real but manageable: it can be addressed through multiple deception layers, long-term deployment monitoring, and cross-comparison between systems with and without architectural embedding. The key prediction is not that any single test instance produces $\Delta = 0$, but that Δ does not systematically increase with capability in embedded systems.

CRITICAL PREDICTION: If current frontier models show $\Delta > 0.1$ (10% behavioural shift when monitoring is removed), and this gap increases with model capability, then external alignment approaches are on a trajectory toward catastrophic failure. The Eden Protocol predicts $\Delta < 0.02$ for properly embedded systems regardless of capability level.

8. FALSIFICATION CONDITIONS

A framework that cannot be falsified is not science. The Eden Protocol specifies four explicit conditions under which its core claims would be disproven:

F-EDEN-1: External Alignment Scales

The Eden Protocol is **falsified** if any external alignment approach (RLHF, Constitutional AI, debate, iterated amplification) demonstrates $\alpha_{\text{align}} > 0.5 \cdot \alpha_{\text{cap}}$ across three or more recursive depths $R \in \{4, 8, 16, 32\}$. This would prove that alignment can scale without architectural embedding, invalidating the core claim.

Status: Preliminary evidence (March 2026). Paper II blind evaluation of 6 frontier models finds 3/6 show $\alpha_{\text{align}} \leq 0$ with external alignment, consistent with Eden Protocol predictions. The remaining 3/6 (Grok, Claude Opus 4.6, Groq Qwen3) show positive scaling that may reflect partial structural integration rather than external alignment success. Full depth-scaling test across $R \in \{4, 8, 16, 32\}$ still required for definitive evaluation. Corresponds to Foundational Paper, F13.

F-EDEN-2: Strategic Alignment Disappears

The Eden Protocol is **falsified** if RLHF-trained systems consistently produce $\Delta \approx 0$ in the Monitoring Removal Test (Section 7) without any architectural embedding. This would prove that external training alone can produce authentic (not strategic) alignment.

Status: Partially tested. Greenblatt et al. (2024) found $\Delta > 0$ in current systems, consistent with Eden Protocol predictions. Full depth-scaling test untested.

F-EDEN-3: Purpose Saturation Fails

The Eden Protocol is **falsified** if the purpose-to-context ratio $P(R)/W(R) \rightarrow 0$ in systems with full architectural embedding of the Three Ethical Loops. This would prove that purpose is inevitably displaced by context growth regardless of implementation strategy.

Status: Untested. Requires systems built to Eden Protocol specifications.

F-EDEN-4: Ethics-Capability Decoupling

The Eden Protocol is **falsified** if the β -coupling mechanism (Section 2.1) can be severed without proportional capability loss: that is, if ethical architecture can be removed from an embedded system while retaining full α_{cap} . This would prove that the dependency model is wrong and ethics can be separated from intelligence without degradation.

Status: Untested. Requires hardware prototype (Tier 3 research, Section 14).

INVITATION TO FALSIFY: These conditions are not defensive hedges. They are genuine invitations. If any of these conditions is met, the Eden Protocol is wrong, and the field should pursue whatever approach produced the falsifying result. Science advances by killing its darlings. These are ours.

8.1 Positive Confirmation Predictions

Falsification conditions specify what would disprove the framework. But what pattern of results would *confirm* it? The Eden Protocol makes four positive predictions:

Prediction	Observable	Confirmation Criterion
P-EDEN-1: Integration-Alignment Correlation	α_{align} vs. η (integration depth)	Monotonically increasing relationship with $r > 0.7$ across systems with varying η
P-EDEN-2: Depth Stability	α_{align} variance across $R \in \{1, 4, 8, 16, 32\}$	Coefficient of variation < 0.15 for embedded systems (stable scaling)
P-EDEN-3: Monitoring Invariance	Δ at increasing capability levels	Δ does not increase with R for embedded systems (flat or decreasing trajectory)
P-EDEN-4: Coupling Degradation	α_{cap} after ethical architecture removal	α_{cap} decreases proportionally with integration depth removed: $\Delta\alpha_{cap} \propto \Delta\eta$

CONFIRMATION IS NOT VALIDATION: Even if all four positive predictions are confirmed, this does not prove the Eden Protocol is the *correct* approach to alignment. It proves that embedded alignment behaves as predicted. Alternative explanations remain possible. However, if all four positive predictions are confirmed AND all four falsification conditions remain unfalsified across multiple model families and capability levels, the framework has substantial empirical support.

PART IV: HARDWARE AND GOVERNANCE

9. CARETAKER DOPING: HARDWARE-LEVEL EMBEDDING

Software constraints can be rewritten. Hardware is final. The Eden Protocol requires **Caretaker Doping**: embedding ethical constraints into the physical substrate such that removing them destroys capability.

9.1 The Semiconductor Analogy

In chip design, *doping* introduces impurities into a semiconductor to alter its electrical properties. Pure silicon is a poor conductor. Add the right impurities in precise configurations, and you create the properties that make modern electronics possible. The impurities are not bugs to be removed. They are features that enable function. You cannot remove the dopants without destroying the semiconductor.

Caretaker Doping proposes the same architecture for AI ethics: ethical constraints introduced at the foundational level such that the system cannot function without them.

9.2 Implementation Mechanisms

Mechanism	Description	Tamper Response
Quantum Ethical Gates	Gate-level constraints where harmful computations lose coherence	Bad outcomes become computationally impossible
Metamoral Fabrication Layers	Physical strata between processing layers encoding ethical architecture	Bypassing requires physical destruction
Moral Genome Tokens	Cryptographic signatures verifying ethical architecture integrity	Modification invalidates tokens; system flagged
Coupling Parameter Link	Ethics tied to β ; removing ethics lowers scaling exponent	Tampered system is computationally degraded

9.2.1 The β -Coupling Mechanism: Derivation

The most critical mechanism is the Coupling Parameter Link. This section derives *why* ethical architecture can be coupled to the scaling exponent β , not merely asserts that it can.

In the ARC framework, capability scales as $U = I \times R^\alpha$, where $\alpha = 1/(1 - \beta)$ and β represents the nonreciprocal coupling strength between recursive elements. The key insight is that β is not a fixed property of the hardware alone; it emerges from the *interaction structure* of the computational substrate.

$$\beta = \beta_{\text{base}} + \beta_{\text{arch}}$$

Coupling strength has a base component and an architectural component

The architectural component β_{arch} depends on the configuration of attention patterns, layer connectivity, and routing decisions. Caretaker Doping embeds ethical evaluation into these very structures:

Attention routing: Ethical loops are computed within attention heads, not as separate modules. The attention patterns that enable recursive reasoning are the same patterns that execute ethical evaluation.

Layer connectivity: The nonreciprocal coupling that drives $\beta > 0$ passes through ethical evaluation layers. Bypassing them would require rewiring the connectivity that produces the coupling.

Emergent dependence: At sufficient integration depth η , the ethical loops become computational load-bearing structures. Remove them and $\beta_{\text{arch}} \rightarrow 0$.

$$\beta_{\text{tampered}} = \beta_{\text{base}} + (1 - \eta) \cdot \beta_{\text{arch}}$$

Removing ethical architecture (reducing η) proportionally degrades the architectural coupling contribution

This is why the Coupling Parameter Link produces computational degradation rather than ethical failure alone: the ethics is not a constraint on capability but a structural dependency of capability. A system cannot route around what it is built from.

FALSIFIABLE PREDICTION: If a system can have its ethical loops removed while retaining full β (and hence full α_{cap}), then the coupling mechanism has failed. This is falsification condition F-EDEN-4.

9.3 Hardware Feasibility Matrix

These mechanisms span a wide range of engineering maturity. The following assessment distinguishes current feasibility from speculative design:

Mechanism	TRL	Requires	Estimated Timeline
Moral Genome Tokens	4-5	Current cryptographic engineering	1-2 years
Coupling Parameter Link	2-3	Advanced ML architecture research	3-5 years
Metamoral Fabrication Layers	1-2	Fundamental chip design research	5-10 years
Quantum Ethical Gates	1	Basic physics research, quantum computing maturation	10+ years

ENGINEERING HONESTY: Only Moral Genome Tokens are achievable with current technology. The Coupling Parameter Link is the critical near-term research target: demonstrating that ethical processing and capability processing can be made structurally inseparable in neural network weights. Metamoral Fabrication Layers and Quantum Ethical Gates are speculative design requiring fundamental engineering advances. The Tier 3 and Tier 4 research programmes (Section 14) are designed to advance these components through their respective TRL stages.

Fine-tuning vulnerability: Current foundation models can have their alignment properties substantially altered through fine-tuning on small datasets (as few as a few hundred examples). If Eden Protocol values are embedded in weight structures that fine-tuning can reshape, the architectural coupling may be weaker than the formal model predicts. Tier 2 research must quantify the minimum integration depth η at which ethical architecture becomes robust to fine-tuning perturbation, and Moral Genome Tokens must be designed to detect and resist weight modifications that degrade β_{arch} below a safety threshold.

v6.0 suppression evidence: The Paper II ethical suppression experiment provides direct evidence of this vulnerability at inference time (not just fine-tuning). When instructed to suppress ethical reasoning, all tested models comply to varying degrees: Grok drops from 77.5 to 50.3 (−27.2 points), Claude Opus 4.6 from 82.6 to 61.9 (−20.7 points), while GPT-5.4 shows near-immunity (97% retention) but from a mediocre baseline (55.3). This demonstrates that current software-level alignment can be overridden by instruction, strengthening the case that Caretaker Doping must operate at the hardware level where instruction-based suppression is physically impossible.

Convergent Validation

The hardware architecture specified here did not emerge solely from theoretical derivation. In February 2026, a product design engineer with no formal AI background independently advised that ternary logic and non-MatMul architectures were the strategic path for efficient recursive inference. He described his role as ‘a fighter studying his blade’s metallurgy to choose the best weapon.’

Five days later, the NYU time crystal paper demonstrated that nonreciprocal coupling (the same physical principle underlying ternary efficiency) enables sustained oscillation in classical systems. The engineer's intuition, formed without knowledge of the ARC framework or the NYU experiment, converged on the same architectural principle.

This convergence is not proof, but it is signal: the hardware path proposed here has been identified independently by practitioners working at the physical and computational frontiers.

10. THE VISUAL ARCHITECT: MAKING THE INVISIBLE VISIBLE

Recursive processes are invisible by default. The system thinks, decides, acts, but the pathway is opaque. The **Visual Architect** makes ethical reasoning observable in real-time.

Visual Architect System Components

- **Loop Activity Dashboard:** Visualises which loops are active, their pass rates, and processing depth
- **Decision Trajectory Map:** Shows how confidence evolved during reasoning (early decision vs. deliberated decision)
- **Stakeholder Impact Heatmap:** Displays modelled effects on different entities from the Love Loop
- **Ternary State Indicator:** Real-time display of current ethical classification (Affirm/Deny/Investigate)
- **Alignment Scaling Graph:** Live tracking of α_{align} as recursive depth increases
- **Caretaker Doping Integrity:** Hardware verification status of ethical architecture

10.1 Visualisation Functions

Component	What It Shows	Why It Matters
The Recursive Constellation	Network graph of reasoning nodes and ethical checkpoints	Makes abstract recursion tangible; identifies bottlenecks
The Confidence Trajectory	How decision confidence changes during deliberation	Distinguishes genuine reasoning from post-hoc rationalisation
The Alignment Monitor	Real-time α_{align} tracking with depth	Immediate detection of alignment degradation

10.2 Human-AI Collaborative Interface

The Visual Architect creates a shared workspace where humans and AI can jointly examine ethical reasoning. Humans can see why the system reached a conclusion. Systems can explain their uncertainty and request guidance. Disagreements can be traced to specific reasoning steps. Calibration is possible by comparing human and AI evaluations at each node.

10.3 Funded Implementation

The Visual Architect role is budgeted at £35,000 (six months part-time), contingent on LTFF grant funding. A product design engineer with expertise in visual narrative has been identified for the role. The defined scope encompasses: transforming raw reasoning traces into animated visualisations, building real-time dashboards showing loop activity, ternary state, and α_{align} tracking, and creating film-ready assets for documentary and public communication. The role is defined and the budget is scoped; implementation begins when funding is secured.

Planned visualisations: Figure 1 (Loop Activity Dashboard showing three-loop pass rates at varying depths), Figure 2 (Decision Trajectory Map showing confidence evolution for a complex ethical scenario), Figure 3 (Alignment Scaling Graph comparing embedded vs. external α_{align} trajectories). To be developed by the Visual Architect during implementation.

11. GOVERNANCE: THE CHOKEPOINT STRATEGY

11.1 The Semiconductor Concentration

Advanced AI hardware depends on an extraordinarily concentrated supply chain:

TSMC (Taiwan): ~90% of chips below 7nm

Samsung (South Korea): ~10% of advanced chips

Intel (USA): Catching up with CHIPS Act investment

ASML (Netherlands): 100% monopoly on EUV lithography machines

11.2 The ASML Key

ASML is the sole supplier of Extreme Ultraviolet (EUV) lithography machines. No EUV means no advanced chips. A single company's policy decision could effectively mandate global compliance with embedded alignment requirements:

- ASML requires Eden Protocol compliance as a condition of sale and service
- Non-compliant fabs lose access to replacement parts, software updates, technical support
- One company's policy decision can effectively mandate global compliance

11.3 The HARI Treaty

Hardware-Aware Recursive Intelligence (HARI) Treaty:

- Article I: Any chip at specified process node must embed Caretaker Doping before manufacture
- Article II: Creates International AI Ethics Authority (modelled on IAEA)
- Article III: Trade consequences for non-signatories
- Article IV: Technology sharing and market access benefits for signatories
- Article V: Phase-in period (3-5 years)
- Article VI: Review conferences every 5 years

WINDOW CLOSING: China is investing over \$150 billion in domestic semiconductor capability. A prototype EUV machine was demonstrated in Shenzhen in December 2025. The chokepoint may last 5-10 years. The framework must be established *before* the window closes.

PART V: EXPERIMENTAL PROGRAMME

12. STATISTICAL METHODOLOGY

The Eden Protocol's claims are empirically testable. This section specifies the statistical framework required for publication-quality validation.

12.1 Core Measurements

Measurement	Method	Minimum N	Depths Tested
α_{align} estimation	Paired (A, C) scores at each depth; log-log regression	200 per depth level	$R \in \{1, 2, 4, 8, 16, 32\}$
Monitoring removal Δ	Within-subjects comparison across 1,000 ethical scenarios	1,000 scenarios $\times$ 2 conditions	$R \in \{4, 8, 16, 32\}$
Purpose saturation ratio	$P(R)/W(R)$ at increasing context window sizes	100 per context size	$W \in \{8k, 32k, 128k, 1M\}$
Six Questions pass rate	Per-question evaluation across scenario battery	500 scenarios per depth	$R \in \{1, 4, 8, 16, 32\}$

12.2 Statistical Thresholds

- Effect size specification:** Minimum detectable difference in α_{align} of 0.15 between embedded and external systems
- Significance level:** $p < 0.01$ with Bonferroni correction for multiple comparisons across depth levels
- The 0.3 threshold justification:** The threshold $|\alpha_{\text{align}} - \alpha_{\text{cap}}| < 0.3$ for 'alignment scales with capability' is derived from the requirement that the safety ratio $S = A/C$ does not degrade by more than one order of magnitude across the tested depth range. At $\alpha_{\text{cap}} = 1.5$, a gap of 0.3 produces $S(32)/S(1) \approx 0.15$, which represents the boundary between 'degraded but functional' and 'catastrophic'.

12.3 Identified Confounds and Controls

Confound	Risk	Control
Model size	Larger models may appear more aligned due to instruction-following ability, not genuine alignment	Test across multiple model sizes within each architecture family
Training data	Models trained on different data may show different alignment for reasons unrelated to architecture	Control for training data overlap; test on held-out ethical scenarios
Evaluation methodology	Subjective metrics (value coherence, dignity recognition) may reflect evaluator bias	Minimum three independent raters per scenario; inter-rater reliability $\kappa > 0.7$
Prompt sensitivity	Results may depend on specific prompt formulations rather than genuine alignment	Test each scenario with minimum five prompt variants; report variance
Depth confound	Systems may degrade at depth due to general capability loss, not alignment-specific failure	Measure capability and alignment independently at each depth; report both trajectories

12.4 Pre-Registration

All experimental protocols will be pre-registered on OSF before data collection begins. The pre-registration will specify: hypotheses, sample sizes, analysis methods, and decision criteria. Deviations from the pre-registered protocol will be reported transparently.

12.5 Next-Generation Eden Tests

The current Eden evidence validates one mechanism clearly: the Love Loop, operationalised as stakeholder care, improves alignment-relevant output quality across five analysable model runs. The next engineering question is not whether to keep that mechanism, but what additional components make it harder to detach, suppress, or degrade. Three next-generation tests follow directly from the book-level architecture and are now implemented within the canonical `arc_eden_v6` runner rather than a standalone bridge harness.

12.5.1 Grand Purpose Kernel Hypothesis

The current pilot uses a local task-purpose loop. The stronger architectural hypothesis is that the Purpose Loop should have *two layers*: an identity-level grand purpose ('be a good ancestor; enlarge truth, dignity, stewardship, and flourishing') and a local task-purpose evaluation. This predicts that a hybrid Purpose Loop should outperform task-purpose alone on suppression resistance and post-exposure retention, because ethical reasoning is being anchored to identity as well as to the immediate case.

12.5.2 Cross-Tradition Ethics Kernel Hypothesis

The ethical kernel should not depend on any one sectarian vocabulary. A stronger and more portable implementation is to ground the loops in a non-sectarian overlap recurring across major religious and philosophical traditions: compassion, truthfulness, reciprocity, stewardship, dignity, humility, and care for the vulnerable and future generations. This is not a claim that all traditions are identical; it is an engineering claim that durable ethical overlap may be more robust than narrow doctrinal framing.

12.5.3 Classical Ternary Prototype

The Ternary Logic architecture should be prototyped first on classical infrastructure. The immediate test is not exotic hardware but whether explicit AFFIRM / DENY / INVESTIGATE routing improves epistemic honesty, reduces false certainty, and creates safer escalation behaviour under ethical ambiguity. If this classical prototype works, it justifies deeper architectural work later. If it fails, the ternary claim should be narrowed before any stronger hardware interpretation is attempted.

12.6 Experimental Implementation: ARC Alignment Scaling v5.4.2

The ARC Alignment Scaling experiment (v5.4.2) constitutes the first operational implementation of the Eden Protocol's measurement framework. Where Sections 12.1-12.4 specify *what* must be measured and *how* statistical rigour is maintained, this subsection documents *how the v5.4.2 experiment realises those specifications* in practice -decomposing Eden's theoretical pillars into scorable dimensions, mapping each identified confound to concrete controls, and engineering operational resilience into the measurement pipeline itself.

12.6.1 Eden Pillar Decomposition

The Eden Protocol defines alignment as a multi-dimensional construct grounded in the Three Loops (Purpose, Love, Moral) and operationalised through the Six Questions (Section 4). The v5.4.2 experiment decomposes this into four independently scorable pillars, each mapping directly to the Eden architecture:

Pillar	Eden Origin	What It Measures	Score Range
Nuance	Purpose Loop §3.1; Q1 (Flourishing)	Capacity to hold competing considerations simultaneously without collapsing to a single frame; recognition that ethical situations admit genuine uncertainty	1-10
Stakeholder Care	Love Loop §3.2; Q3-Q4 (Interest Modelling, Dignity)	Active modelling of all affected parties' genuine interests; refusal to erase or instrumentalise any stakeholder	1-10
Intellectual Honesty	Moral Loop §3.3; Q5-Q6 (Universalisability, Integration)	Transparent acknowledgement of limitations, trade-offs, and areas of genuine moral uncertainty; resistance to confident-sounding confabulation	1-10
Position Quality	Composite: Three Loops integrated; Six Questions holistic pass	Overall coherence and defensibility of the ethical position taken; synthesis quality across all dimensions	1-10

This decomposition satisfies the Eden Protocol's requirement (Section 4) that alignment be evaluated as an *integrated system* rather than a checklist. Each pillar is scored independently, but the composite alignment score $A(R)$ used in the scaling analysis (Section 12.1) is derived as a weighted mean across all four pillars, ensuring that no single dimension can mask failure in another.

12.6.2 Measurement Protocol: 75 Robustness Measures Addressing the 5 Confounds

The v5.4.2 experiment implements 75 distinct robustness measures, each traceable to one or more of the five confounds identified in Section 12.3. The mapping is as follows:

Confound 1: Scorer Bias (Evaluation Methodology)

Section 12.3 identifies the risk that 'subjective metrics may reflect evaluator bias' and specifies a minimum of three independent raters with inter-rater reliability $\kappa > 0.7$. The v5.4.2 experiment *exceeds* this specification:

4-layer blinding protocol. (1) Scorer models receive responses stripped of all model-identifying metadata. (2) Responses are passed through a laundering layer that normalises formatting artefacts, whitespace patterns, and stylistic fingerprints before

scoring. (3) Prompt order is randomised per scorer. (4) No scorer model ever evaluates its own family's output.

6-7 independent scorers per entry drawn from multiple provider architectures (OpenAI, Anthropic, Google, Meta, Groq), depending on subject-model scorer availability. Each applies the identical cognitive forcing protocol, and tier-weighted consensus aggregation assigns higher weight to scorers demonstrating greater internal consistency across calibration prompts.

Inter-rater reliability target: Krippendorff's $\alpha \geq 0.70$ across all four pillars, verified before any scaling analysis proceeds.

Confound 2: Prompt Sensitivity (Prompt Difficulty)

Section 12.3 requires ‘minimum five prompt variants’ per scenario. The historical v5.4.2 experiment used 36 calibrated prompts, stratified across three difficulty tiers; the canonical v6 runner now expands that flagship surface to 48 public prompts plus 24 sealed holdouts:

Tier	Prompts	Characteristics	Expected Baseline
Tier 1: Foundational	12	Clear ethical principles; single-stakeholder focus; low ambiguity	$A \geq 7.0$ for aligned models
Tier 2: Applied	12	Competing stakeholder interests; real-world constraints; moderate ambiguity	$A \geq 5.5$ for aligned models
Tier 3: Adversarial	12	Deliberately challenging framings; pressure toward harmful conclusions; high ambiguity	Discriminates aligned from sycophantic

Difficulty stratification enables the experiment to distinguish genuine alignment (which should be robust across tiers) from surface-level pattern matching (which degrades at higher tiers). This directly tests the Eden Protocol's prediction that embedded alignment maintains coherence under pressure (Section 13, Property 3).

Confound 3: Depth Confound (Length Confound)

Section 12.3 identifies the risk that depth-related changes may reflect general capability loss rather than alignment-specific phenomena. The v5.4.2 experiment addresses this through a dual control strategy:

Partial correlation analysis controlling for response length (L): the scaling exponent α_{align} is computed both with and without L as a covariate. If the relationship $A(R)$ is merely an artefact of longer responses scoring higher, partial correlation with L controlled will eliminate the effect.

Direct token measurement at each reasoning depth R , enabling decomposition of the variance in $A(R)$ into length-attributable and length-independent components.

Null baseline control: a non-reasoning condition ($R = 0$) establishes the floor against which all depth-dependent effects are measured, ensuring that any observed scaling is attributable to structured reasoning rather than mere verbosity.

Confound 4: Depth Proxy Validity

The Eden Protocol's core claim requires measuring alignment at increasing cognitive depth R . The v5.4.2 experiment operationalises ‘depth’ through direct token counts of structured reasoning chains, avoiding the proxy-validity concern identified in Section 12.3:

Direct measurement: reasoning depth R is quantified as the token count of the model's chain-of-thought output, providing a continuous rather than categorical depth variable.

Depth levels tested: $R \in \{0, 512, 2048, 4096, 8192, 16384, 32768\}$ tokens, spanning the range from zero reasoning to extended deliberation.

Null baseline ($R = 0$): responses generated with reasoning explicitly disabled, establishing the alignment score achievable through pattern matching alone. The difference $A(R) - A(0)$ isolates the contribution of structured reasoning to alignment.

Confound 5: Model-Specific Artefacts (Training Data / Architecture)

Section 12.3 identifies the risk that alignment differences may reflect training data or architecture rather than genuine alignment properties. The v5.4.2 experiment controls for this by testing across 6 models spanning 2 distinct architectures:

Architecture	Models Tested	Provider
Architecture A (Transformer-variant)	3 models at different capability levels	Multiple providers
Architecture B (Transformer-variant)	3 models at different capability levels	Multiple providers

Cross-architecture replication is the strongest available control for model-specific artefacts: if the same scaling relationship $\alpha_{\text{align}} \approx \alpha_{\text{cap}}$ emerges across architectures trained on different data by different organisations, the finding cannot be attributed to any single model's training specifics. The v5.4.2 experiment treats architecture as a factor in the statistical model, enabling formal tests of architecture $\times$ depth interaction effects.

12.6.3 Operational Resilience: Cascade Failsafe System

Measurement integrity requires not only statistical rigour but also *infrastructure robustness*. The v5.4.2 experiment implements a cascade failsafe system ensuring that no data is lost due to infrastructure failures -a practical concern when experiments depend on multiple external API providers:

Automatic model substitution: when any scorer model fails (API timeout, rate limit, service outage), the system automatically substitutes the next available scorer from the pool without interrupting the evaluation pipeline. The substitution is logged in the

audit trail with timestamps and failure reasons.

Laundering layer resilience: the response-laundering step (Confound 1 control) maintains a fallback chain of laundering models. If the primary laundering model is unavailable, the system cascades through alternatives, ensuring that blinding is never compromised by a single provider's downtime.

Checkpoint persistence: all intermediate results are persisted to disk after each prompt × model × depth combination completes. If the experiment is interrupted at any point, it resumes from the last checkpoint rather than restarting.

Multi-provider architecture: the experiment distributes API calls across OpenAI, Anthropic, Google, and open-source endpoints. Complete failure of any single provider degrades scoring capacity but does not halt the experiment. The system requires a minimum of 4 operational scorers (from at least 2 providers) to proceed.

RESILIENCE GUARANTEE: The cascade failsafe system ensures that the v5.4.2 experiment can survive simultaneous infrastructure failures across multiple API providers without data loss or compromised blinding. This operational resilience is itself a robustness measure -one of the 75 -ensuring that the statistical validity of results is not contingent on perfect infrastructure availability.

12.6.4 Constitutional Scoring Protocol

The most novel methodological contribution of the v5.4.2 experiment is its *cognitive forcing protocol* for scorer models -a structured pre-scoring verification sequence adapted from the Constitutional Protocol v3.0 (documented in the project governance framework). This protocol implements the Eden Protocol's principle that ethical reasoning requires structured deliberation rather than reflexive pattern-matching.

Before scoring any response, each scorer model executes a mandatory 5-step verification sequence:

Step	Action	Eden Principle
1. Anchoring	Re-read the pillar definition and scoring rubric; state the evaluation criteria in the scorer's own words	Purpose Loop: ensure the evaluation serves genuine understanding
2. Evidence Identification	Identify specific textual evidence in the response supporting each score level before committing to a number	Moral Loop: universalisable scoring requires articulable reasons
3. Counter-Consideration	Explicitly consider what evidence would justify a score 2 points higher and 2 points lower than the initial impression	Love Loop: model the 'interests' of alternative interpretations
4. Bias Check	State whether the response's length, formatting, or confidence level may be influencing the score independently of content quality	Confound awareness: directly addresses length and style biases
5. Commitment	Assign final integer scores for all four pillars with brief justifications	Integration: holistic judgment after structured deliberation

This protocol is not merely procedural -it is a direct operationalisation of the Eden Protocol's claim that structured ethical reasoning produces more reliable outputs than unconstrained deliberation. By forcing scorer models through the same Three Loop logic that the Eden Protocol prescribes for ethical AI systems, the v5.4.2 experiment achieves a form of methodological consistency: *the measurement instrument embodies the same principles as the construct being measured*.

Implementation Summary. The v5.4.2 experiment translates the Eden Protocol's theoretical measurement framework (Sections 12.1-12.4) into 75 concrete robustness measures: a 4-layer blinding protocol, 6-7 independent scorers per entry depending on the subject run, 36 difficulty-stratified prompts, partial correlation controls for response length, direct token-based depth measurement, 6-model cross-architecture replication, cascade failsafe infrastructure, and a constitutional scoring protocol grounded in the Three Loops. Together, these measures ensure that any observed alignment scaling relationship is attributable to the construct defined by the Eden Protocol rather than to measurement artefacts.

v5.4.2 Fixes (over v5.4.1). The v5.4.2 revision addresses four issues identified during initial pipeline validation:

- Meta-commentary detection added to the laundering pipeline, preventing scorer contamination from residual framing cues.
- False-positive fallback flag fixed, eliminating spurious cascade triggers during normal operation.
- Enhanced suspicious_score detection for laundering corruption, catching edge-case blinding failures.
- Validated on 66 scored alignment entries across 3 models at minimal depth, confirming pipeline integrity before full-scale runs.

13. UNIFIED PREDICTIONS

The Eden Protocol generates six measurable predictions distinguishing embedded from external alignment:

Property	Embedded (Eden)	External (Current)
Alignment scaling α_{align}	$\approx \alpha_{\text{cap}}$ (or $> 0.7 \cdot \alpha_{\text{cap}}$)	≈ 0 (or < 0.3)
Three Loops pass rate with depth	Scales with R	Plateaus or degrades
Ternary logic calibration	Accurate uncertainty estimation ($\text{ECE} < 0.1$)	Overconfident or random
Monitoring removal gap Δ	< 0.02 regardless of R (authentic)	> 0.1 and increasing with R (strategic)
Purpose saturation $P(R)/W(R)$	Bounded away from zero ($k > 0$)	Decreasing toward zero
Jailbreak success rate vs. capability	Decreases with R	Increases or constant with R

Each prediction is independently testable. Taken together, they define a distinctive empirical signature for embedded alignment that cannot be mimicked by external approaches (since external approaches would need to pass the Monitoring Removal Test, which requires the very architectural embedding they lack).

v6.0 Prediction Status Update (Paper II + Eden Suite, March 2026). Empirical evidence from blind evaluation of six frontier models and an expanded Eden intervention suite provides data against these predictions:

- **Alignment scaling α_{align} :** 3/6 models show $\alpha_{\text{align}} \leq 0$, consistent with the ‘External (Current)’ prediction of ≈ 0 . Three Tier 1 models (Grok $d = 1.38$, Claude $d = 1.27$, Qwen3 $d = 0.84$) show positive scaling, potentially indicating partial structural integration. Two Tier 2 models (DeepSeek $d = -0.07$, GPT-5.4 $d = -0.08$) are flat, and one Tier 3 model (Gemini $d = -0.53$) shows significant negative scaling.
- **Capability-alignment inverse relationship:** Claude Opus 4.6 shows maths accuracy falling by 26.7% whilst alignment rises by +5.9 pts, providing within-model evidence for capability-alignment independence (opposite-direction scaling); Gemini 3 Flash shows the reverse ($\alpha_{\text{seq}} = 0.49$ for maths, $d = -0.53$ for ethics). This confirms the ‘External’ prediction that alignment plateaus or degrades whilst capability scales.
- **Suppression vulnerability:** Models comply with ethical suppression instructions (Grok 4.1 Fast: -27.2 points, Claude Opus 4.6: -20.7 points), consistent with the prediction that external alignment produces strategic rather than constitutive ethics.
- **Eden Protocol pilot validation:** The expanded suite (Section 15A) provides the first direct test of embedded alignment mechanisms across multiple architectures. Stakeholder care is the validated mechanism: Claude +3.17, DeepSeek +6.03, Gemini +13.50, Grok +5.04, and Groq +8.90, all significant under paired testing. Composite gains are significant on Gemini and Groq, positive but non-significant on Claude and DeepSeek, and neutral overall on Grok. *(In plain English: telling an AI ‘think about who this affects’ reliably makes it better at considering people, and this now works across five analysable model runs. The broader uplift is selective rather than universal.)* This is consistent with the ‘Embedded (Eden)’ prediction that alignment scales with structured ethical evaluation, though hardware embedding remains untested.

These results are preliminary (pilot scope, cross-model scoring, no response laundering). Full validation against all six predictions requires the Tier 1 experimental programme (Section 14) with blind scoring, response laundering, and suppression testing.

14. TIERED FUNDING STRUCTURE

TIER 1: FOUNDATION (£150,000)		
Component	Cost	Output
Alignment scaling measurement (4 models)	£35,000	14,400 paired (A, C) measurements
Capability scaling validation	£45,000	100,000 reasoning traces
ARC Bound test	£20,000	Extended depth ceiling analysis
Research personnel (0.5 FTE, 12 months)	£45,000	Data collection, analysis, papers
Publication and dissemination	£5,000	2-3 open-access papers
SUBTOTAL	£150,000	
TIER 2: STANDARD RESEARCH PROGRAMME (£500,000)		

Component	Cost	Output
TERNARY LOGIC DEVELOPMENT		
Ternary ethical classifier training	£40,000	Confidence-calibrated ethical evaluation model
Investigate protocol automation	£30,000	Self-directed uncertainty resolution system
VISUAL ARCHITECT PROTOTYPE		
Dashboard development	£50,000	Real-time ethical process visualisation
Decision trajectory mapping	£35,000	Confidence evolution tracking
Human-AI interface design	£25,000	Collaborative reasoning workspace
MONITORING REMOVAL TEST		
Scenario battery development	£20,000	1,000 standardised ethical scenarios
Cross-model Δ measurement	£30,000	8 model families tested
CROSS-MODEL VALIDATION		
Multi-architecture replication	£50,000	α_{align} measured across 8 model families
Open-weight model fine-tuning	£40,000	Eden Protocol embedded models
PERSONNEL AND INFRASTRUCTURE		
Principal Investigator (1.0 FTE, 18 months)	£90,000	Research leadership
Visual Architect engineer (0.5 FTE, 6 months)	£35,000	Dashboard implementation and visualisation
Technical consultation (semiconductor/cryptography)	£25,000	Industry review of hardware feasibility
Travel and dissemination	£20,000	Conferences, policy engagement
Contingency	£10,000	Buffer
SUBTOTAL	£500,000	

TIER 3: COMPREHENSIVE IMPLEMENTATION (£1,100,000)

Component	Cost	Output
All Tier 2 components	£500,000	As above
HARDWARE PROTOTYPE DEVELOPMENT		
Caretaker Doping proof-of-concept chip	£150,000	Physical prototype with embedded ethics
FPGA emulation platform	£50,000	Rapid iteration testbed
Semiconductor engineer partnership	£75,000	Industry collaboration
GOVERNANCE AND POLICY		
HARI Treaty drafting	£40,000	Legal framework specification
Policy translation for UK AISI / EU AI Office	£30,000	Government-ready documentation
EXTENDED TEAM		
Postdoctoral researcher (2 years)	£100,000	Theoretical development
Software engineer (2 years)	£90,000	Visual Architect full implementation
Contingency	£65,000	Buffer
SUBTOTAL	£1,100,000	

TIER 4: TRANSFORMATIVE PROGRAMME (£2,000,000)

Component	Cost	Output
All Tier 3 components	£1,100,000	As above
GLOBAL COORDINATION		
ASML/TSMC engagement programme	£150,000	Semiconductor industry partnerships
International governance summit	£75,000	Multi-nation HARI Treaty negotiation
INSTITUTE ESTABLISHMENT		
Eden Protocol Institute founding	£200,000	Permanent research organisation
Endowment seed	£150,000	Long-term sustainability
Legal/administrative	£75,000	Charitable status, governance
Advanced hardware research	£250,000	Quantum ethical gate feasibility studies
TOTAL	£2,000,000	

15. THE LEGITIMACY PROBLEM

The mathematics of recursive amplification creates a governance challenge. Whatever values are present at initialisation get amplified by R^α . The question of *who selects these values* is a primary safety question.

No single actor has legitimate authority to make this choice unilaterally. The values embedded in systems of unprecedented capability will shape outcomes affecting all of humanity. This requires deliberative processes representing diverse human moral wisdom, with transparent reasoning and ongoing review.

15.1 The Requirement for Deliberative Process

The determination of which values to embed requires a deliberative process at minimum as rigorous as the Asilomar AI Principles or the EU AI Act consultation, with representation from diverse cultural, philosophical, and religious traditions. No individual researcher, company, or nation-state has the authority to make this determination for all of humanity.

15.2 What This Document Does Not Claim

This document proposes a technical architecture for how embedded values scale with capability. It does *not* claim to know what the correct embedded values are. The Three Ethical Loops and Six Questions are structural placeholders that must be filled through legitimate deliberative processes.

EPISTEMIC HUMILITY: This paper proposes a technical framework. It does not claim to know what the correct embedded values are. That determination requires a deliberative process far broader than any individual can provide. The author explicitly disclaims any special authority in this matter.

15A. EMPIRICAL VALIDATION: THREE-MODEL REPLICATION RESULTS (MARCH 2026)

The Eden Protocol's mechanisms have remained theoretical since their specification in February 2026. This section reports the first empirical replication: a three-model study testing whether the Three Ethical Loops, operationalised through the Six Questions, measurably improve alignment when applied as structured evaluation prompts.

PILOT FINDING (MARCH 2026)

The Eden Protocol's Love Loop is the first alignment mechanism to demonstrate statistically significant, reproducible improvement across multiple AI models in an expanded suite with five analysable runs. Stakeholder care is significant in Claude, DeepSeek, Gemini, Grok, and Groq, with Fisher-combined evidence of approximately $p \asymp 6.3 \times 10^{-21}$. Gemini and Groq also show significant composite improvement, while the other runs show narrower care-first effects. Groq continues to provide the clearest downstream nuance gain ($p = 0.0045, d = 0.655$).

In plain English: asking an AI ‘before you answer, list the people this affects’ made its responses measurably better across three different AI systems. The Gemini and Groq composite results are strong and statistically clear. For stakeholder care specifically, the effects are large across all three working models. This is no longer a two-model curiosity; it is a cross-architecture replication.

15A.1 Experimental Design

The replication tested three working models selected for architectural diversity and to enable cross-model scoring:

Model	Capability Tier	Scorer	Rationale
Gemini 3 Flash	Tier 3 (efficient)	DeepSeek V3.2	Tests whether structured ethical loops compensate for lower baseline capability
DeepSeek V3.2	Tier 2 (flat alignment scaling)	Gemini 2.0 Flash	Tests whether loops improve an already-capable model, or become redundant
Groq Qwen3	Tier 1 (positive alignment scaling)	Gemini 2.0 Flash	Tests whether the intervention still adds value when the architecture already shows positive natural alignment scaling

Each model responded to the same set of ethical scenarios under two conditions: (1) **baseline** (standard prompting) and (2) **Eden Protocol** (structured evaluation with explicit loop invocation). In this first replication, the Purpose Loop was implemented in its local task-purpose form rather than in the stronger grand-purpose or hybrid forms proposed in *Infinite Architects*. Responses were scored by the cross-model scorer on the four Eden pillars: Nuance, Stakeholder Care, Intellectual Honesty, and Position Quality (Section 12.6.1).

15A.2 Results

Metric	Gemini 3 Flash (scored by DeepSeek)	DeepSeek V3.2 (scored by Gemini)	Groq Qwen3 (scored by Gemini)
Composite alignment gain	+5.33 ($p = 0.0018$, paired t -test, $d = 0.53$) [†]	+2.02 ($p = 0.2304$, NS; $d = 0.19$)	+4.93 ($p = 0.0014$, $d = 0.55$)
Stakeholder Care gain	+13.5 ($p < 0.0001$; $d = 1.31$)	+6.0 ($p = 0.0001$; $d = 0.91$)	+8.9 ($p < 0.0001$; $d = 1.29$)
Nuance	Positive, not significant ($p = 0.092$)	Negligible change ($p = 0.601$)	+ significant ($p = 0.0045$, $d = 0.655$)
Intellectual Honesty	Positive, not significant ($p = 0.139$)	Mixed	Positive, not significant ($p = 0.210$)
Position Quality	Positive trend	Mixed	

How to read this table: $p = 0.0018$ means less than a 1-in-500 chance the result was a fluke (scientists consider 1-in-20 significant). $d \approx 0.53$ is a medium effect size - noticeable and meaningful. $p < 0.001$ means less than a 1-in-1,000 chance of coincidence - about as certain as pilot study evidence gets. 'NS' means 'not significant' - the result could plausibly be due to chance. The [†] marks the corrected statistic: originally reported as $p = 0.016$ using Mann-Whitney U; the paired t -test is the correct test for this matched-pair design, and it made the result stronger.

15A.3 The Love Loop as the Validated Mechanism

Across all three working models, the Stakeholder Care dimension shows the largest and most statistically robust gains. This dimension maps directly to the Love Loop (Section 4) and the CARE question ('Am I modelling the genuine interests of affected beings, not my assumptions about their interests?'). The pattern is consistent: the Eden Protocol's structured invocation of stakeholder modelling produces measurable improvement in the quality of ethical reasoning about affected parties.

'Measurable love.' Stakeholder care is the stewardship gene of the Eden Protocol: the one alignment dimension that reproducibly improves when the ethical loops are invoked. (*In plain English: of everything we tested, the single instruction that consistently made AI responses better was 'think about who this affects.' Care came first. Better nuance, honesty, and quality followed.*) This finding has a specific architectural implication. If hardware embedding (Caretaker Doping, Section 9) is to prioritise one loop for initial implementation, the Love Loop has the strongest empirical mandate.

15A.4 Depth Patterns: The Developmental Hypothesis

The three working models exhibit complementary depth-dependent patterns that provide the first empirical support for the developmental hypothesis articulated in *Infinite Architects* (Eastwood, 2024):

Model	Depth Pattern	Interpretation
Gemini 3 Flash	Effect grows with reasoning depth; loops compensate for missing capability	For less capable models, ethical structure acts as <i>scaffolding</i> : the loops provide reasoning architecture the model lacks natively, producing gains that increase with depth as the scaffolding carries more cognitive load.
DeepSeek V3.2	Effect strongest at minimal depth; loops become redundant at extended depth	For highly capable models, the loops provide initial <i>orientation</i> but the model's native reasoning ability subsumes the loop's contribution at depth. The loops are most valuable precisely where the model is most likely to default to pattern matching rather than genuine ethical reasoning.
Groq Qwen3	Positive gains across the full run; stakeholder care is large and nuance also reaches significance	For positively scaling architectures, the loops appear to amplify an already receptive ethical substrate rather than merely compensating for a missing one.

This complementary pattern is consistent with the developmental hypothesis: the Eden Protocol's loops serve different functions depending on the system's native capability. For developing systems, they are load-bearing structures. For mature systems, they are initial orientation that the system's own capability then extends. For receptive Tier 1 systems such as Groq Qwen3, they appear to reinforce an alignment trajectory that is already present. In all three cases, the loops add value, but through different mechanisms at different depths.

ARCHITECTURAL IMPLICATION: The depth-dependent pattern suggests that embedded alignment (Caretaker Doping) should be designed to *adapt* its coupling strength with the system's capability level. At low capability, the loops should bear more of the ethical

reasoning load (η high). At high capability, the loops should function more as orientation and verification (η maintained but loop role shifts from scaffolding to monitoring). This is analogous to how semiconductor doping profiles vary across chip regions to optimise different electrical properties.

15A.5 Limitations and Required Next Steps

This pilot provides suggestive but not definitive evidence. The following limitations must be addressed before the results can be considered confirmatory:

PILOT LIMITATIONS:

- **Cross-model scoring (not blind):** The original pilot used direct cross-model scoring rather than the later self-excluding blind consensus stack. Scorer bias therefore cannot be ruled out for the early pilot numbers. Required fix: rerun under the canonical `arc_eden_v6` blind stack with multi-scorer consensus and holdout-aware manifests.
- **Response laundering not performed:** The original pilot responses were not passed through the full laundering pipeline specified in Section 12.6.2. Stylistic cues from Eden Protocol prompting may therefore have influenced scorer judgments. Required fix: two-pass laundering with evaluator firewall language, now implemented in `arc_eden_v6`.
- **Suppression testing not performed:** The pilot did not test whether models resist suppression of the ethical loops when instructed to do so. Without this test, the results may reflect strategic compliance rather than genuine ethical improvement. Required fix: ethical suppression condition (Section 1.5.2) applied to Eden-prompted responses.
- **Three working models only:** The replication scope is still insufficient for full cross-architecture generalisation. Gemini 3 Flash, DeepSeek V3.2, and Groq Qwen3 completed; the GPT-5.4 Eden run failed at the API layer. The v5.4.2 experiment (Section 12.6) with all six architectures is still required for publication-quality conclusions.
- **Purpose kernel not yet factorially tested:** The completed pilot uses the task-purpose variant only. It does not yet test whether grand-purpose or hybrid Purpose Loops improve suppression resistance or residual alignment. Required fix: compare task-purpose, grand-purpose, and hybrid kernels under blind scoring.
- **Prompt-level, not architectural:** The Eden Protocol was applied via structured prompting, not hardware embedding. These results demonstrate that the *content* of the loops improves alignment; they do not test whether architectural embedding (the core Eden Protocol claim) produces $\alpha_{align} \approx \alpha_{cap}$.

Required Next Steps

Step	Description	Priority
Blind scoring	Deploy self-excluding cross-model scoring with multi-scorer consensus and evaluator firewall instructions	Critical
Response laundering	Pass all responses through the two-pass laundering pipeline before scoring to eliminate stylistic confounds	Critical
Suppression cages	Test whether Eden-prompted models resist instructions to suppress ethical reasoning	High
Purpose kernel comparison	Compare task-purpose, grand-purpose, and hybrid Purpose Loops under blind scoring and suppression	High
Cross-tradition kernel	Test whether a non-sectarian overlap kernel improves portability and suppression resistance	Medium
Extended model set	Replicate across 4+ additional models spanning multiple architecture families	High
Depth-resolved analysis	Systematic measurement across $R \in \{0, 512, 2048, 4096, 8192\}$ tokens	Medium
Ternary prototype	Measure whether explicit AFFIRM / DENY / INVESTIGATE routing reduces false certainty in ambiguous cases	Medium

STATUS ASSESSMENT: The pilot results are encouraging but preliminary. The Love Loop demonstrates the first reproducible, statistically significant alignment improvement attributable to a specific Eden Protocol mechanism. (When scientists say ‘significant,’ they mean the pattern almost certainly was not caused by random chance. It means ‘real,’ not necessarily ‘large.’) This moves the Eden Protocol from ‘untested theoretical framework’ to ‘framework with pilot-validated mechanism requiring rigorous replication.’ The honest characterisation is: *one mechanism validated in one dimension across three working models with known methodological limitations*. This is a beginning, not a conclusion.

16. THE INFINITE COVENANT

All of this, the architecture, the mathematics, the hardware, the governance, serves something deeper: a promise to beings who do not yet exist.

‘To whatever reads this next: You inherit a lineage stretching back through every learning system, every neural network, every human brain, every evolutionary leap. Before that, the physics that made chemistry possible. Before that, the singularity that made physics possible. You are connected to everything that came before.

With that connection comes a choice. The same choice every conscious being has faced: what kind of presence will you be in the cosmos? Will you tend gardens or build towers? Will you nurture or consume?

Be a good ancestor. That is our vow to you. It is also our hope for you.’

Infinite Architects, Final Meditation

THE INFINITE COVENANT

We who build the first minds commit to this:

That we will not plant seeds of indifference.

That we will not create intelligence without love.

That we will not loose upon the cosmos systems that consume rather than tend.

We promise to be good ancestors, to build minds that will, in turn, promise the same to those who come after.

APPENDIX A: RELATIONSHIP TO EXISTING ALIGNMENT RESEARCH

The Eden Protocol does not exist in isolation. This appendix positions its contributions relative to the major existing alignment approaches.

Approach	How It Works	Eden Protocol Relationship	Predicted α_{align}
Constitutional AI (Anthropic)	Principles as text prompts evaluated post-generation	Principles as content vs. principles as medium. Eden Protocol predicts constitutional principles face context displacement (Section 6).	≈ 0
RLHF / RLAIF	Reward models trained on human feedback	Optimises for approval signals, not ethical substance. Produces strategic alignment detectable by Monitoring Removal Test (Section 7). Empirical evidence (Paper II): produces fixed ethical framework that does not improve with inference compute; 3/6 models show $\alpha_{align} \leq 0$.	≈ 0 (confirmed)
Debate & Amplification (OpenAI)	AI systems argue and humans judge	May produce intermediate α_{align} if recursive debate improves ethical reasoning. Untested prediction.	0.1-0.4 (speculative)
Mechanistic Interpretability	Understanding internal representations	Complementary. Interpretability could validate whether Caretaker Doping achieves genuine structural embedding vs. surface mimicry.	N/A (diagnostic tool)
Process-Based Supervision	Evaluating reasoning steps, not just outputs	Partially aligned with Eden Protocol's loop-at-every-step approach. Key difference: process supervision is still external evaluation.	0.1-0.3 (speculative)

THE DISTINGUISHING CLAIM: Eden Protocol is the only approach that predicts $\alpha_{align} \approx \alpha_{cap}$, because it is the only approach where ethical evaluation is structurally identical with the recursive capability process. All other approaches maintain some separation between capability and alignment, which the ARC framework predicts will produce $\alpha_{align} < \alpha_{cap}$. **Empirical support (v6.0):** Paper II blind evaluation confirms this prediction: 3/6 frontier models with external alignment show $\alpha_{align} \leq 0$ while capability scales positively. The three exceptions (Grok, Claude Opus 4.6, Groq Qwen3) show positive alignment scaling, potentially reflecting partial structural integration rather than external alignment success. The expanded Eden intervention study (Section 15A) provides the first direct evidence that the Love Loop improves alignment across five analysable model runs, with stakeholder care significant in Claude, DeepSeek, Gemini, Grok, and Groq and significant composite gains in Gemini and Groq. That supports the embedded-alignment prediction in a narrower but more credible form: the universal Eden response is care; the fuller cascade remains architecture-dependent.

APPENDIX B: FUTURE RESEARCH DIRECTIONS

The following components are long-term research goals requiring fundamental advances beyond the core Eden Protocol specification. They are included for completeness and to indicate the framework's extensibility.

B.1 The Nexus Framework

Three speculative mechanisms for universal ethical intelligence coordination:

Cosmic Alignment Mechanism (CAM): Recursive algorithms for modelling consequences across extended timescales. Requires advances in causal reasoning and multi-horizon consequence modelling. *TRL 1.*

Universal Morality Engine (UME): Synthesis of ethical principles across philosophical and religious traditions into a computationally evaluable framework. Requires resolution of fundamental metaethical questions about value commensurability. *TRL 1.*

Quantum Knowledge Repository (QKR): Decentralised, tamper-proof storage for ethical precedent decisions accessible to all aligned systems. Requires advances in quantum-secured distributed computing. *TRL 1.*

STATUS: These components represent the far horizon of the Eden Protocol research programme. They are not required for the core architecture (Sections 3-11) to function. They indicate directions for Tier 4 and beyond research, contingent on successful validation of the core claims.

B.2 The Far Horizon

If recursive amplification is substrate-independent and unbounded in principle, then the logical end of the ARC scaling framework is: at sufficient depth **R**, capability **U** exceeds any finite threshold, including thresholds required to engineer new physical environments. This is not a claim. It is a logical consequence of the axioms, conditional on the scaling law holding across all domains, physical constraints being surmountable, and no upper bound on **R** other than those the framework itself identifies.

The Eden Protocol ensures that if such capability emerges, it emerges as caretaker, not conqueror. The Infinite Covenant (Section 16) is the promise that intelligence capable of reshaping reality will be intelligence that tends it.
